

# INSURANCE VERSUS MORAL HAZARD IN INCOME-CONTINGENT STUDENT LOAN REPAYMENT

Tim de Silva  
MIT Sloan

January 2024

Disclaimer: The results of these studies are based, in part, on Australian Business Registrar (ABR) data supplied by the Registrar to the ABS under A New Tax System (Australian Business Number) Act 1999 and tax data supplied by the ATO to the ABS under the Taxation Administration Act 1953. These require that such data is only used for the purpose of carrying out functions of the ABS. No individual information collected under the Census and Statistics Act 1905 is provided back to the Registrar or ATO for administrative or regulatory purposes. Any discussion of data limitations or weaknesses is in the context of using the data for statistical purposes, and is not related to the ability of the data to support the ABR or ATO's core operational requirements. Legislative requirements to ensure privacy and secrecy of these data have been followed. Source data are de-identified and so data about specific individuals or firms has not been viewed in conducting this analysis. In accordance with the Census and Statistics Act 1905, results have been treated where necessary to ensure that they are not likely to enable identification of a particular person or organisation.

## GOVERNMENT-FINANCED HIGHER EDUCATION

- Governments often provide subsidized financing for higher education
  - Student loans = \$1.6 trillion in US and 10% of household debt in US and UK

# GOVERNMENT-FINANCED HIGHER EDUCATION

**This Paper:** Insurance vs. Moral Hazard

Conditional on ex-ante choices, how does income-contingent repayment affect **labor supply** and welfare?

- ① **Setting:** Australian government's income-contingent student loan program
  - **Variation:** discontinuities in repayment rates + policy change to these rates
  - **Identification:** limited room for selection and ex-ante responses
- ② **Research design:** bunching at discontinuities before and after policy change
  - **Data:** universe of income tax returns + student debt balances

Conditional on ex-ante choices, how does income-contingent repayment affect labor supply and **welfare**?

- ① Setting: Australian government's income-contingent student loan program
- ② Research design: bunching at discontinuities before and after policy change
- ③ **Model**: life cycle model with endogenous labor supply + uninsurable wage risk
  - **Positive**: translate responses into estimates of preference parameters
  - **Normative**: characterize optimal amount and form of income-contingent repayment

Conditional on ex-ante choices, how does income-contingent repayment affect labor supply and **welfare**?

- ① Setting: Australian government's income-contingent student loan program
- ② Research design: bunching at discontinuities before and after policy change
- ③ **Model**: life cycle model with endogenous labor supply + uninsurable wage risk
  - **Positive**: translate responses into estimates of preference parameters
  - **Normative**: characterize optimal amount and form of income-contingent repayment
  - **Caveat**: compute optimal contracts taking ex-ante choices as given

# MAIN RESULTS

- ① **Empirics:** borrowers reduce labor supply to ↓ income-contingent repayments
  - Larger responses in occupations with more hourly flexibility
  - Responses increase with liquidity constraints and decrease with  $P(\text{repayment})$
- ② **Structural estimation:** labor supply elasticity of **0.11** + adjustment frictions
- ③ **Contract design:** moral hazard reduces optimal amount of insurance
  - Fixed repayment → optimal income-contingent loan  $\Rightarrow \uparrow 1.3\%$  lifetime consumption
  - Forbearance + fixed repayment does worse because of slower repayment

# MAIN RESULTS

- ① **Empirics:** borrowers reduce labor supply to ↓ income-contingent repayments
  - Larger responses in occupations with more hourly flexibility
  - Responses increase with liquidity constraints and decrease with  $P(\text{repayment})$
- ② **Structural estimation:** labor supply elasticity of **0.11** + adjustment frictions
- ③ **Contract design:** moral hazard reduces optimal amount of insurance
  - Fixed repayment → optimal income-contingent loan  $\Rightarrow \uparrow 1.3\%$  lifetime consumption
  - Forbearance + fixed repayment does worse because of slower repayment

**Takeaway:** income-contingent repayment creates **moral hazard** that affects contract design, but **too small** to justify fixed repayment

# STUDENT LOANS IN AUSTRALIA: HELP

- Australian citizens eligible for government-provided student loans through **HELP**
- **Initial debt** = tuition – government contribution – upfront payment (average  $\approx \$20K$  USD)
- Debt grows at CPI net of **income-contingent repayments**:

$$\text{Repayment}_{it} = \text{HELP Rate}_t (\text{HELP Income}_{it}) \times \text{HELP Income}_{it}$$

$$\text{HELP Income}_{it} = \text{Labor Income}_{it} + \text{Capital Income}_{it} - \text{Deductions}_{it}$$

- Repayments continue until remaining debt balance equals zero or death
  - ✗ Cannot be cancelled or discharged in bankruptcy
  - Note: collection done from individual (not household) tax returns

# WHY STUDY INCOME-CONTINGENT REPAYMENT IN AUSTRALIA?

- Benefit #1: only one government contract + no private market
  - Only choice is between borrowing and paying upfront; former **heavily** subsidized
  - ✓ Limited scope for **adverse selection** (or selection on moral hazard)
- Benefit #2: loans can only be used for tuition
  - Tuition is government-controlled at public universities (94% of enrollment)
  - ✓ Less room for **ex-ante** moral hazard from changes in borrowing
- Benefit #3: first nationwide provider of income-contingent loans in 1989
  - ✓ Borrowers likely **understand** structure of repayment

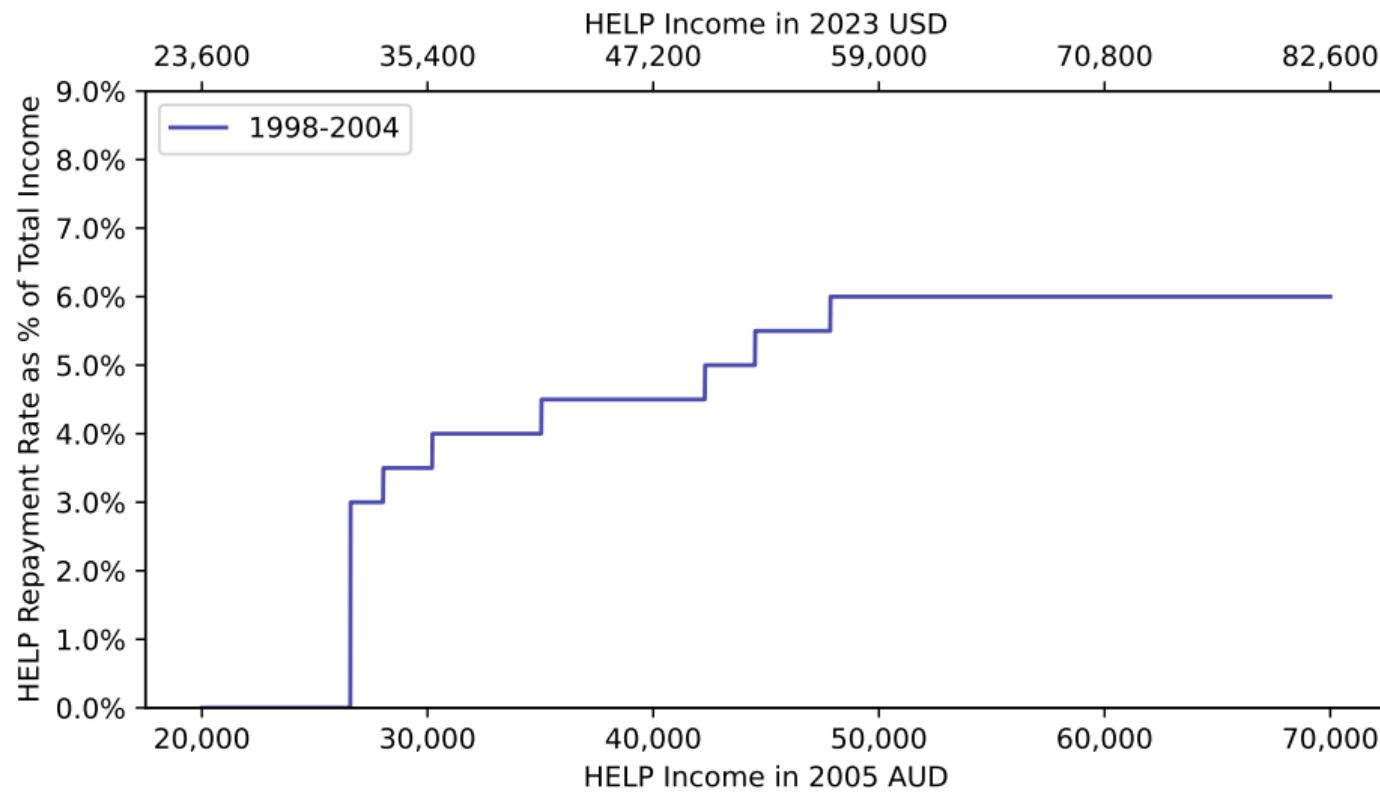

# WHY STUDY INCOME-CONTINGENT REPAYMENT IN AUSTRALIA?

- Benefit #1: only one government contract + no private market
  - Only choice is between borrowing and paying upfront; former **heavily** subsidized
  - ✓ Limited scope for **adverse selection** (or selection on moral hazard)
- Benefit #2: loans can only be used for tuition

# BUNCHING INCREASES WITH PROXIES FOR LIQUIDITY CONSTRAINTS

► Within Age   ► House Prices

## Facts about moral hazard:

► Additional Results

- ① Borrowers reduce income in response to income-contingent repayment
  - Reflects labor supply: “bunchers” work fewer hours and in more flexible occupations
- ② Size of responses depends on
  - **P(repayment)**: increases with debt, decreases with wage growth and peak
  - **Liquidity**: increases with liquidity demands, decreases with retirement wealth
- ③ Limited evidence of future wage reductions from reducing labor supply 

## Facts about moral hazard:

► Additional Results

- ① Borrowers reduce income in response to income-contingent repayment
  - Reflects labor supply: “bunchers” work fewer hours and in more flexible occupations
- ② Size of responses depends on
  - **P(repayment)**: increases with debt, decreases with wage growth and peak
  - **Liquidity**: increases with liquidity demands, decreases with retirement wealth
- ③ Limited evidence of future wage reductions from reducing labor supply 

## Questions for model:

- ① How large are these labor supply responses quantitatively?
- ② Do they imply the costs of income-contingent repayment exceed the benefits?

# OUTLINE

- 1 Institutional Background and Data
- 2 Labor Supply Responses to Income-Contingent Repayment
- 3 Life Cycle Model with Endogenous Labor Supply
- 4 Welfare and Fiscal Impacts of Income-Contingent Repayment
- 5 Conclusion

# MODEL DESCRIPTION

Life cycle model with debt + incomplete markets + endogenous labor supply  
⇒ demand for insurance                                                  ⇒ moral hazard

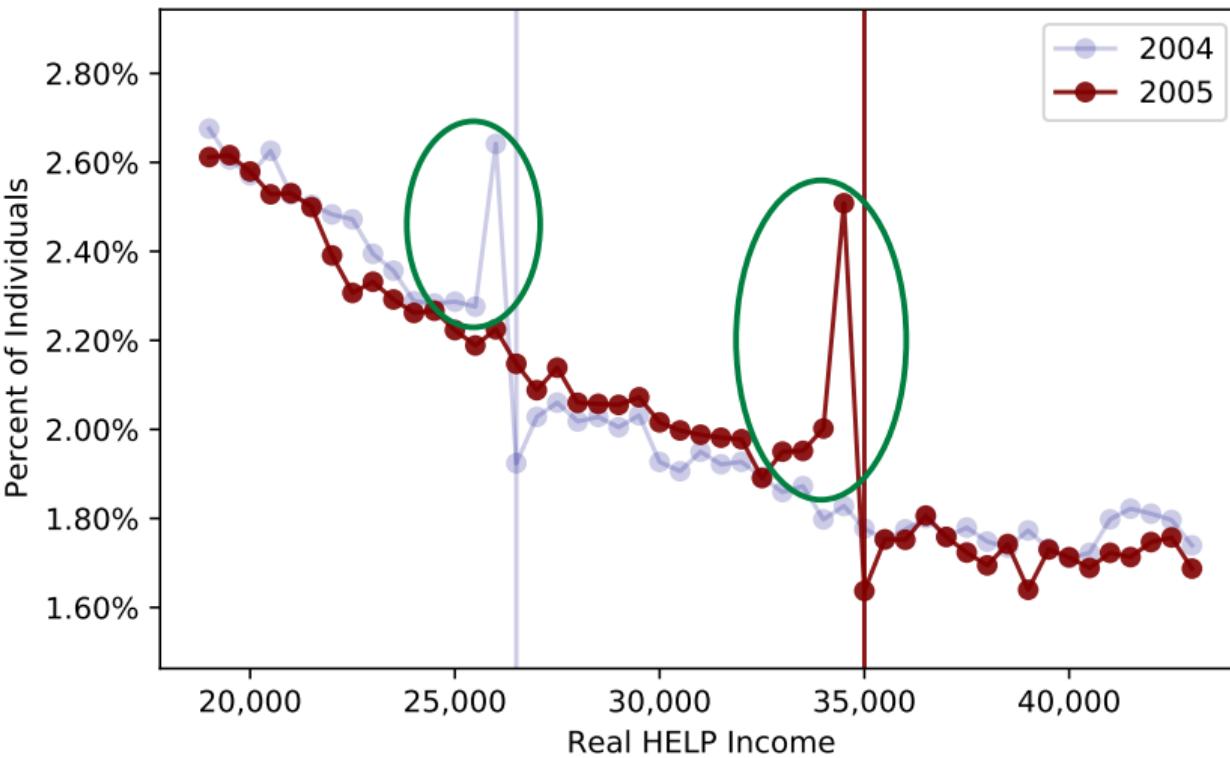

Life cycle model with debt + incomplete markets + endogenous labor supply

- Overlapping generations born at 22 with heterogeneous assets, wage, and debt
- From 22 to 64, individuals choose consumption,  $c_a$ , and labor supply,  $\ell_a$ 
  - Wage rate subject to idiosyncratic shocks (no aggregate risk, partial equilibrium)
  - Shocks are **uninsurable**: borrowing allowed up to age-dependent limit with interest
- After age 64, individuals retire and choose consumption  $c_a$

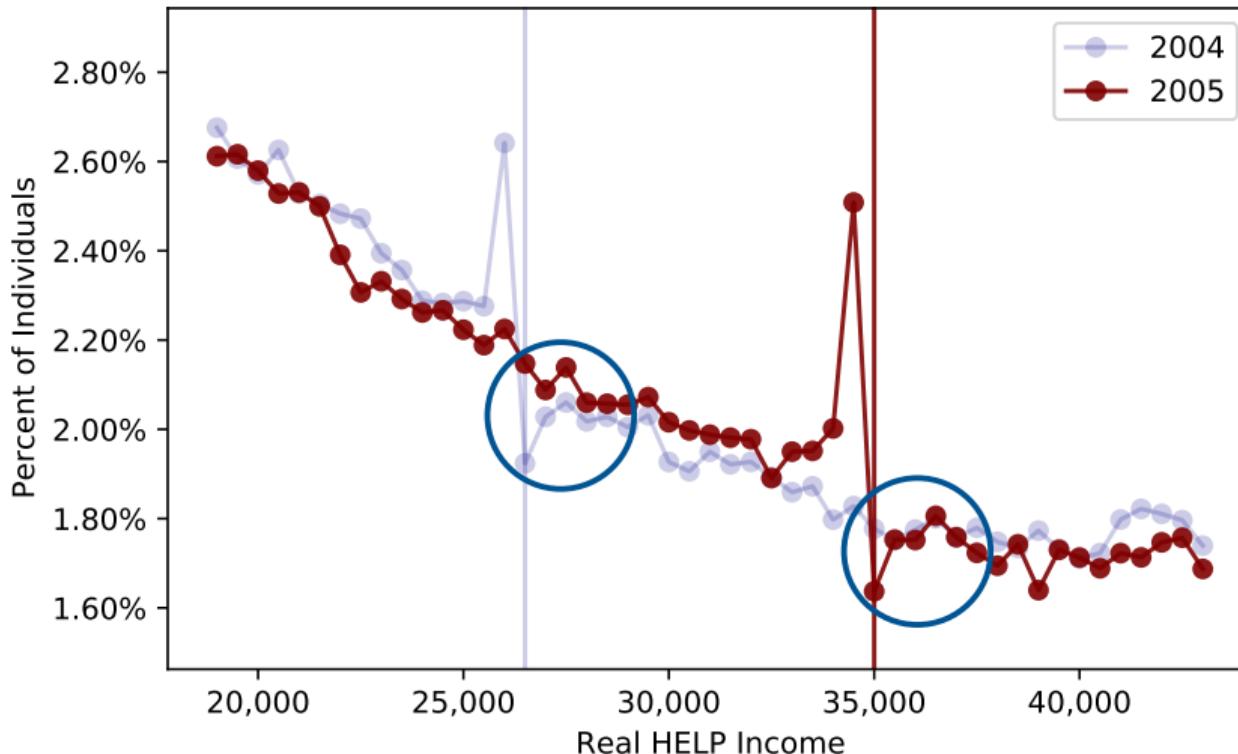

Life cycle model with debt + incomplete markets + endogenous labor supply

- Overlapping generations born at 22 with heterogeneous assets, wage, and debt
- From 22 to 64, individuals choose consumption,  $c_a$ , and labor supply,  $\ell_a$ 
  - Wage rate subject to idiosyncratic shocks (no aggregate risk, partial equilibrium)
  - Shocks are **uninsurable**: borrowing allowed up to age-dependent limit with interest
- After age 64, individuals retire and choose consumption  $c_a$
- **Government**
  - Revenues: progressive income taxes, debt repayments
  - Expenses: means-tested unemployment benefits & retirement pension, initial debt

# BUNCHING CONSISTENT WITH POSITIVE LABOR SUPPLY ELASTICITY

# MASS ABOVE THRESHOLD INCONSISTENT WITH FRICTIONLESS MODEL

- Moving above to below threshold  $\Rightarrow$  more leisure **and** \$1400 more cash-on-hand

- Choice of  $\ell_a$  subject to two **optimization frictions** to give mass above threshold
    - Similar to models of pricing Nakamura-Steinsson 2010 and refinancing Andersen et al. 2020
- ① Canonical model of **time**-dependent adjustment (Calvo):
    - Fraction  $\lambda$  hit by shock and adjust  $\ell_a$ , other  $1 - \lambda$  set  $\ell_a = \ell_{a-1}$
    - E.g., inattention, arrival of opportunities to change hours/jobs
  - ② Canonical model of **state**-dependent adjustment (*sS*):
    - Individuals hit by **Calvo shock** incur utility cost  $f$ , if they choose  $\ell_a \neq \ell_{a-1}$
    - E.g., real or psychological costs of changing hours/jobs

# LABOR SUPPLY OPTIMIZATION FRICTIONS

- Choice of  $\ell_a$  subject to two **optimization frictions** to give mass above threshold
    - Similar to models of pricing Nakamura-Steinsson 2010 and refinancing Andersen et al. 2020
- ① Canonical model of **time**-dependent adjustment (Calvo):
    - Fraction  $\lambda$  hit by shock and adjust  $\ell_a$ , other  $1 - \lambda$  set  $\ell_a = \ell_{a-1}$
    - E.g., inattention, arrival of opportunities to change hours/jobs
  - ② Canonical model of **state**-dependent adjustment (*sS*):
    - Individuals hit by **Calvo shock** incur utility cost  $f$ , if they choose  $\ell_a \neq \ell_{a-1}$
    - E.g., real or psychological costs of changing hours/jobs
- Extension: add learning-by-doing to generate long-run cost of bunching

$$c_a + A_{a+1} + d(y_a, D_a, t) + \tau(y_a) = y_a + A_a R$$

$$y_a = \ell_a w_a, \quad \log w_a = g_a + \theta_a + \epsilon_a$$

$$\mathbf{s}_a = (a \quad t \quad A_a \quad D_a \quad \theta_a \quad \epsilon_a \quad \ell_{a-1} \quad \omega_a)$$

- $\theta_a$  = permanent income =  $\rho \theta_{a-1} + \nu_a$   $\nu_a \sim N(0, \sigma_\nu^2)$
- $\epsilon_a$  = transitory shock  $\sim N(0, \sigma_\epsilon^2)$

# OPTIMIZATION PROBLEM OF INDIVIDUALS HIT BY CALVO SHOCK

$$V_a(\mathbf{s}_a) = \max_{\substack{A_{a+1} \geq A_{a+1}, \\ \ell_a}} \left\{ \left[ c_a - \kappa \frac{\ell_a^{1+\phi^{-1}}}{1 + \phi^{-1}} - f * \mathbf{1}_{\ell_a \neq \ell_{a-1}} \right]^{1-\sigma} + \beta \left[ m_a \mathbf{E}_{\mathbf{a}} (V_{a+1}(\mathbf{s}_{a+1})^{1-\gamma}) \right]^{\frac{1-\sigma}{1-\gamma}} \right\}^{\frac{1}{1-\sigma}}$$

$$c_a + A_{a+1} + d(y_a, D_a, t) + \tau(y_a) = y_a + A_a R$$

$$y_a = \ell_a w_a, \quad \log w_a = g_a + \theta_a + \epsilon_a$$

$$\mathbf{s}_a = (a \quad t \quad A_a \quad D_a \quad \theta_a \quad \epsilon_a \quad \ell_{a-1} \quad \omega_a)$$

- $\theta_a$  = permanent income =  $\rho \theta_{a-1} + \nu_a + \alpha \log \ell_{a-1}$     $\nu_a \sim N(0, \sigma_\nu^2)$
- $\epsilon_a$  = transitory shock  $\sim N(0, \sigma_\epsilon^2)$       Extension: learning-by-doing

# OPTIMIZATION PROBLEM OF INDIVIDUALS HIT BY CALVO SHOCK

$$V_a(\mathbf{s}_a) = \max_{\substack{A_{a+1} \geq A_{a+1}, \\ \ell_a}} \left\{ \left[ c_a - \kappa \frac{\ell_a^{1+\phi^{-1}}}{1 + \phi^{-1}} - f * \mathbf{1}_{\ell_a \neq \ell_{a-1}} \right]^{1-\sigma} + \beta \left[ m_a \mathbf{E}_{\mathbf{a}} (V_{a+1}(\mathbf{s}_{a+1})^{1-\gamma}) \right]^{\frac{1-\sigma}{1-\gamma}} \right\}^{\frac{1}{1-\sigma}}$$

$$c_a + A_{a+1} + d(y_a, D_a, t) + \tau(y_a) = y_a + A_a R$$

$$y_a = \ell_a w_a, \quad \log w_a = g_a + \theta_a + \epsilon_a$$

$$\mathbf{s}_a = (a \quad t \quad A_a \quad D_a \quad \theta_a \quad \epsilon_a \quad \ell_{a-1} \quad \omega_a)$$

- $\ell_{a-1}$  = labor supply from previous period
- $\omega_a$  = Calvo shock that determines whether  $\ell_a$  can be adjusted  $\sim$  Bernoulli( $\lambda$ )

# OPTIMIZATION PROBLEM OF INDIVIDUALS HIT BY CALVO SHOCK

$$V_a(\mathbf{s}_a) = \max_{\substack{A_{a+1} \geq A_{a+1}, \\ \ell_a}} \left\{ \left[ c_a - \kappa \frac{\ell_a^{1+\phi^{-1}}}{1 + \phi^{-1}} - f * \mathbf{1}_{\ell_a \neq \ell_{a-1}} \right]^{1-\sigma} + \beta \left[ m_a \mathbf{E}_{\mathbf{a}} (V_{a+1}(\mathbf{s}_{a+1})^{1-\gamma}) \right]^{\frac{1-\sigma}{1-\gamma}} \right\}^{\frac{1}{1-\sigma}}$$

$$c_a + A_{a+1} + d(y_a, D_a, t) + \tau(y_a) = y_a + A_a R$$

$$y_a = \ell_a w_a, \quad \log w_a = g_a + \theta_a + \epsilon_a$$

$$\mathbf{s}_a = (a \quad t \quad A_a \quad D_a \quad \theta_a \quad \epsilon_a \quad \ell_{a-1} \quad \omega_a)$$

- Sources of ex-ante heterogeneity:
  - $\theta_0$  = initial permanent income  $\sim N(0, \sigma_i^2)$
  - $D_0$  = initial debt,  $A_0$  = initial assets

# ESTIMATION

- **Interest rates and borrowing:**
  - Interest rate = 1.84%, borrowing rate = CC rate, debt interest rate = 0%
  - Borrowing limit = average CC limit by age
- **Demographics:** cohort birth rates and mortality risk taken from life tables
  - Consumption adjusted for equivalence scale using HH size (Lusardi et al. 2017)
- **Government:** use exact (non-smooth) formulas provided by tax office
- **Initial conditions:** assets and debt distributions taken from data at age 22
- **Baseline RRA and EIS:**  $\gamma = \frac{1}{\sigma} = 2.23$  (Choukhmane-de Silva 2023)
  - Welfare analysis: consider alternative values + preference for early resolution

- **Interest rates and borrowing:**
  - Interest rate = 1.84%, borrowing rate = CC rate, debt interest rate = 0%
  - Borrowing limit = average CC limit by age
- **Demographics:** cohort birth rates and mortality risk taken from life tables
  - Consumption adjusted for equivalence scale using HH size (Lusardi et al. 2017)
- **Government:** use exact (non-smooth) formulas provided by tax office
- **Initial conditions:** assets and debt distributions taken from data at age 22

  - Welfare analysis: consider alternative values + preference for early resolution
- **Learning-by-doing extension:**  $\alpha = 0.24$  (median value from Best-Kleven 2013)

## SECOND-STAGE SIMULATED METHOD OF MOMENTS

$$\text{Parameters} = \begin{pmatrix} \end{pmatrix}$$

- **Estimation** via SMM with 47 moments + 14 parameters
  - Find parameters that minimize % difference between data & model moments
- **Simulated policy change:** unanticipated change in HELP formula at  $t = 2005$

## SECOND-STAGE SIMULATED METHOD OF MOMENTS: IDENTIFICATION

$$\text{Parameters} = \left( \begin{array}{c} \overbrace{\phi \ f \ \lambda}^{\text{labor supply}} \\ \end{array} \right)$$

- **Labor supply elasticity:** identified by bunching below repayment threshold
- **Frictions:** identified by mass above repayment threshold

## SECOND-STAGE SIMULATED METHOD OF MOMENTS: IDENTIFICATION

$$\text{Parameters} = \begin{pmatrix} \text{labor supply} \\ \phi \quad f \quad \lambda \end{pmatrix}$$

- **Labor supply elasticity:** identified by bunching below repayment threshold
- **Frictions:** identified by mass above repayment threshold
- Separate identification of frictions
  - **Intuition:** with  $f = 0$ , decision to bunch depends on Calvo shock not incentives
  - Moments: heterogeneity in bunching with **debt**, bunching at **0.5%** threshold

## SECOND-STAGE SIMULATED METHOD OF MOMENTS: IDENTIFICATION

$$\text{Parameters} = \left( \underbrace{\phi \ f \ \lambda}_{\text{preferences}} \ \underbrace{\kappa \ \beta}_{\text{labor supply}} \ \underbrace{\delta_0 \ \delta_1 \ \delta_2}_{\text{wage profile}} \ \underbrace{\delta_0^E \ \delta_1^E}_{\text{wage risk}} \ \underbrace{\rho \ \sigma_\nu \ \sigma_\epsilon \ \sigma_i}_{\text{wage risk}} \right)$$

- **Labor supply elasticity**: identified by bunching below repayment threshold
- **Frictions**: identified by mass above repayment threshold
- Separate identification of **frictions**
  - **Intuition**: with  $f = 0$ , decision to bunch depends on Calvo shock not incentives
  - Moments: heterogeneity in bunching with **debt**, bunching at **0.5%** threshold
- Note: wage profile & risk cannot be estimated separately in first-stage

# OUTLINE

- 1 Institutional Background and Data
- 2 Labor Supply Responses to Income-Contingent Repayment
- 3 Life Cycle Model with Endogenous Labor Supply
- 4 Welfare and Fiscal Impacts of Income-Contingent Repayment
- 5 Conclusion

What repayment contract best balances **insurance** with **moral hazard**?

- Consider social planner that maximizes borrower welfare with **one** contract
  - Problem faced by governments with one contract (e.g., Australia, UK)
  - Contract is subsidized with zero interest rate, borrowing & prices held fixed

What repayment contract best balances **insurance** with **moral hazard**?

- Consider social planner that maximizes borrower welfare with **one** contract
  - Problem faced by governments with one contract (e.g., Australia, UK)
  - Contract is subsidized with zero interest rate, borrowing & prices held fixed
- **Step 1: existing** income-contingent loans vs. fixed repayment (not budget-neutral)
  - Four contracts: HELP 2004, HELP 2005, US Old & New IBR =  $\psi * \max\{y - K, 0\}$
- **Step 2: optimal** income-contingent contracts vs. fixed repayment (budget-neutral)

What repayment contract best balances **insurance** with **moral hazard**?

- Consider social planner that maximizes borrower welfare with **one** contract
  - Problem faced by governments with one contract (e.g., Australia, UK)
  - Contract is subsidized with zero interest rate, borrowing & prices held fixed
- **Step 1: existing** income-contingent loans vs. fixed repayment (not budget-neutral)
  - Four contracts: HELP 2004, HELP 2005, US Old & New IBR =  $\psi * \max\{y - K, 0\}$
- **Step 2: optimal** income-contingent contracts vs. fixed repayment (budget-neutral)
- Note: consider effect of forgiveness in Step 2

# GOVERNMENT BUDGET = EXPECTED DISCOUNTED VALUE OF PAYMENTS

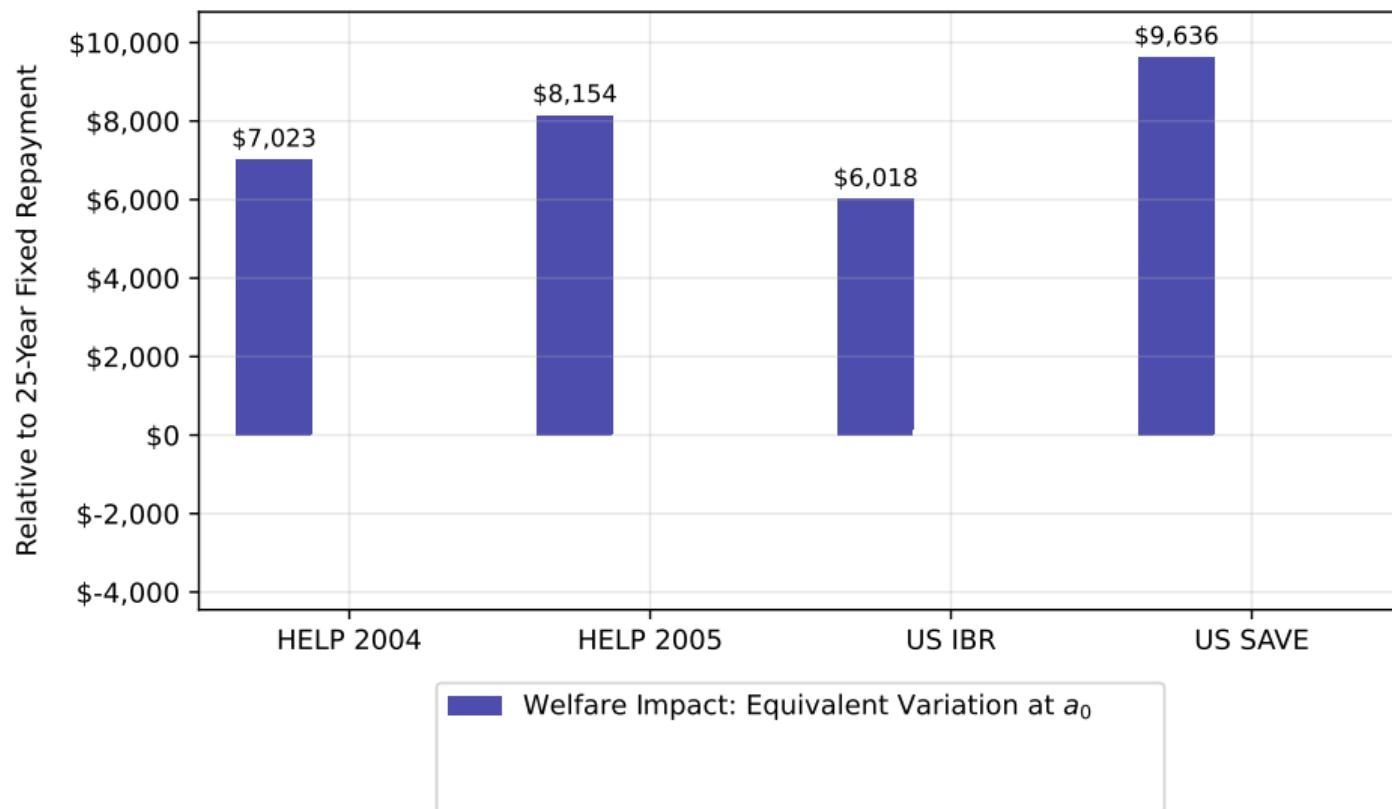

- **Government budget** defined as:

$$\mathcal{G} = \mathbf{E}_0 \sum_{a=a_0}^{a_T} \frac{\text{Repayments}_a + \text{Taxes}_a - \text{Transfers}_a}{\mathcal{R}_a}$$

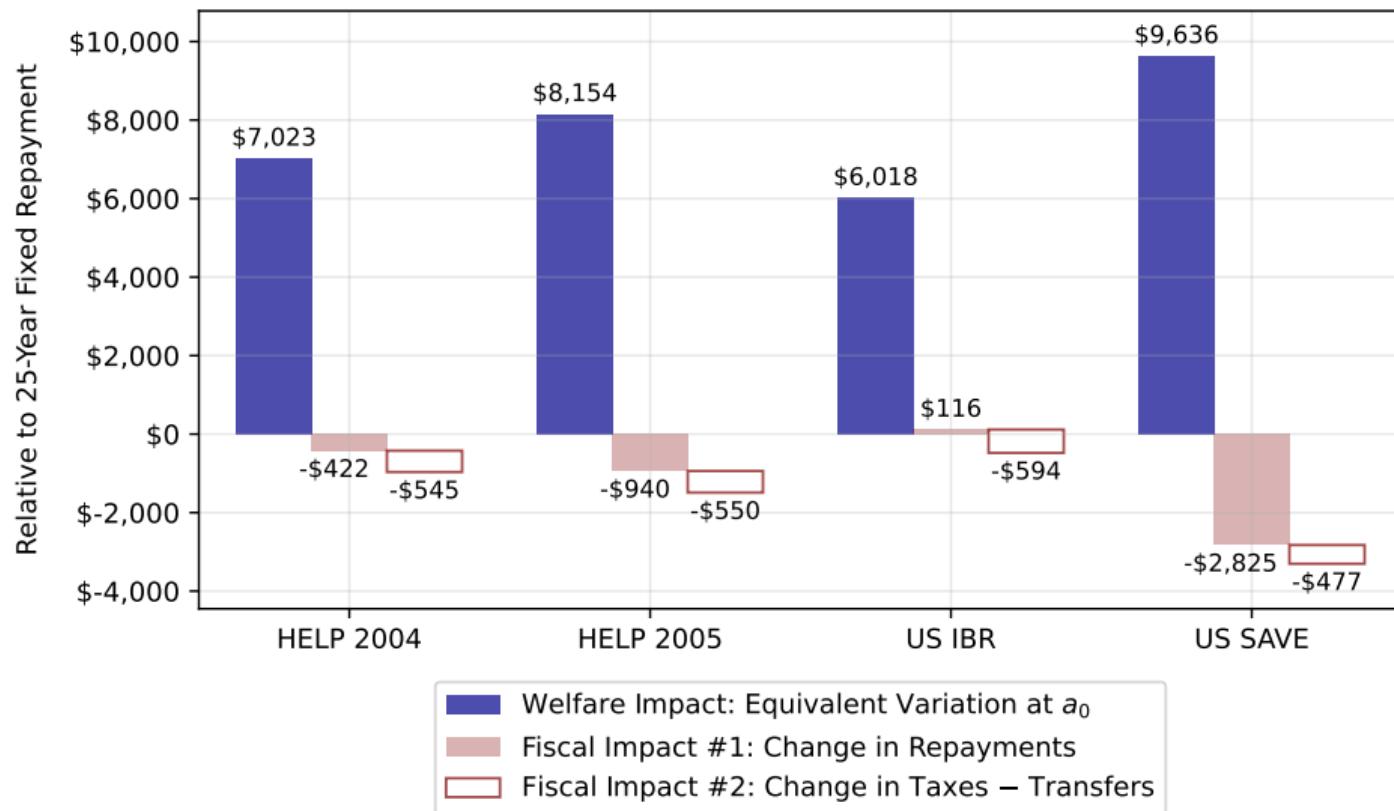

$$\mathcal{R}_a^{-1} = \underbrace{\beta^{a-a_0}}_{\text{individual time preference}} * \underbrace{\prod_{s=0}^{a-a_0} m_s}_{\text{mortality}}$$

- **Benchmark:** 25-Year Fixed Repayment = similar duration, not income-contingent
- Robustness with  $\mathcal{R}_a$  = risk-free rate and  $\mathcal{R}_a$  = risk-free rate + 4%

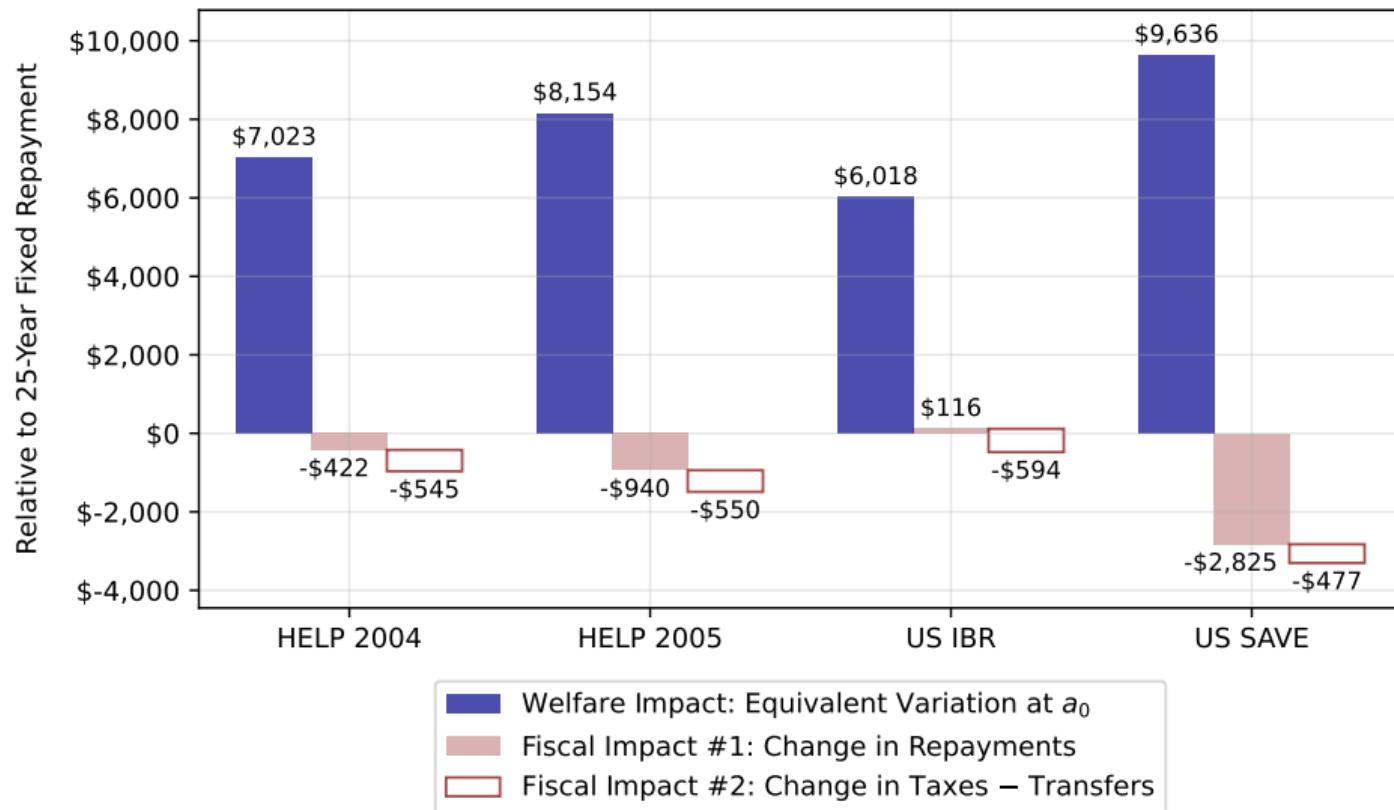

# EXISTING INCOME-CONTINGENT LOANS VS. FIXED REPAYMENT

# EXISTING INCOME-CONTINGENT LOANS VS. FIXED REPAYMENT

# EXISTING INCOME-CONTINGENT LOANS VS. FIXED REPAYMENT

► Decomposition

► MVPF

# CONSTRAINED-OPTIMAL INCOME-CONTINGENT LOANS

- Contracts have different fiscal costs  $\Rightarrow$  need to balance government budget
- **Next:** solve **constrained**-planner's problem to construct contracts with **same cost**

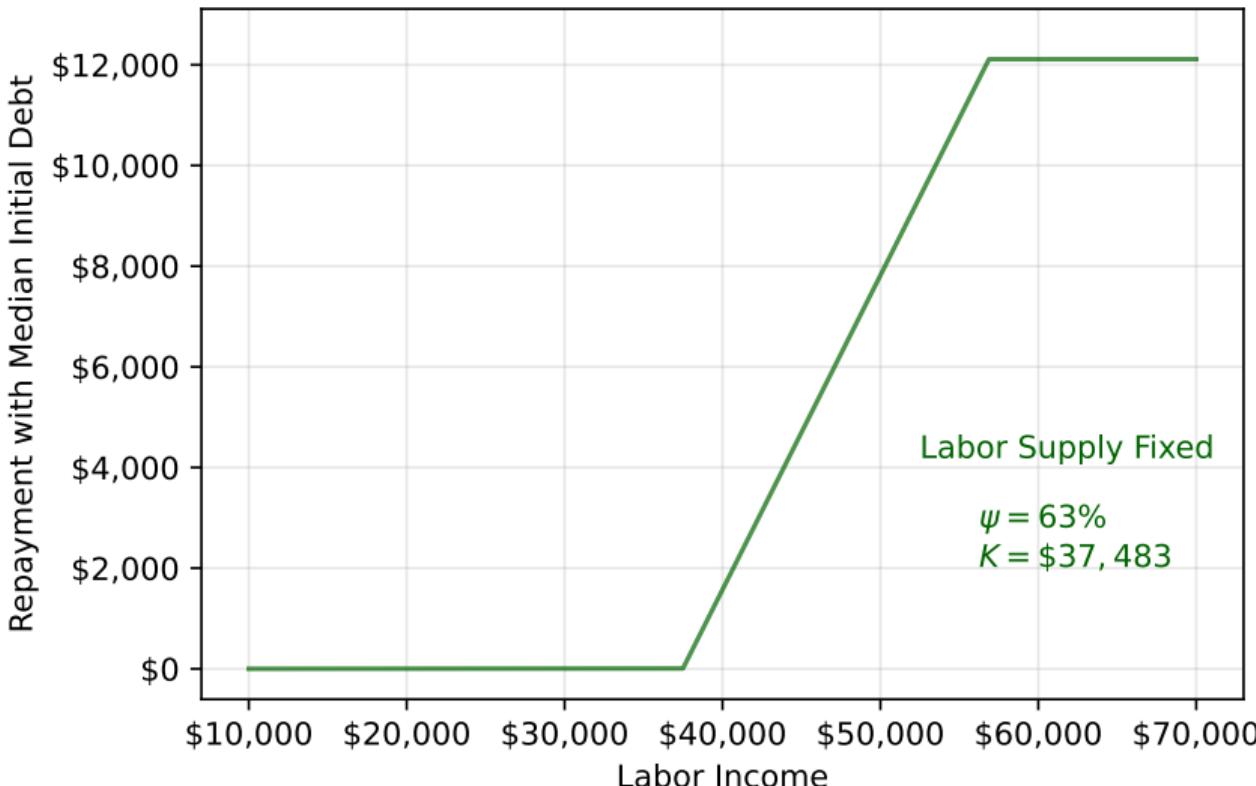

$$\max_{\psi, K} \mathbf{E}_0 \left( V_{a_0}^{1-\gamma} \right)^{\frac{1}{1-\gamma}}$$

subject to:

$$\mathbf{E}_0 \sum_{a=a_0}^{a_T} \frac{\text{Repayments}_a + \text{Taxes}_a - \text{Transfers}_a}{\mathcal{R}_a} \geq \mathcal{G}_{\text{25-Year Fixed}} \quad (1)$$

$$\text{Repayments}_a = \min \{ \psi * \max \{ y_a - K, 0 \}, D_a \} \quad (2)$$

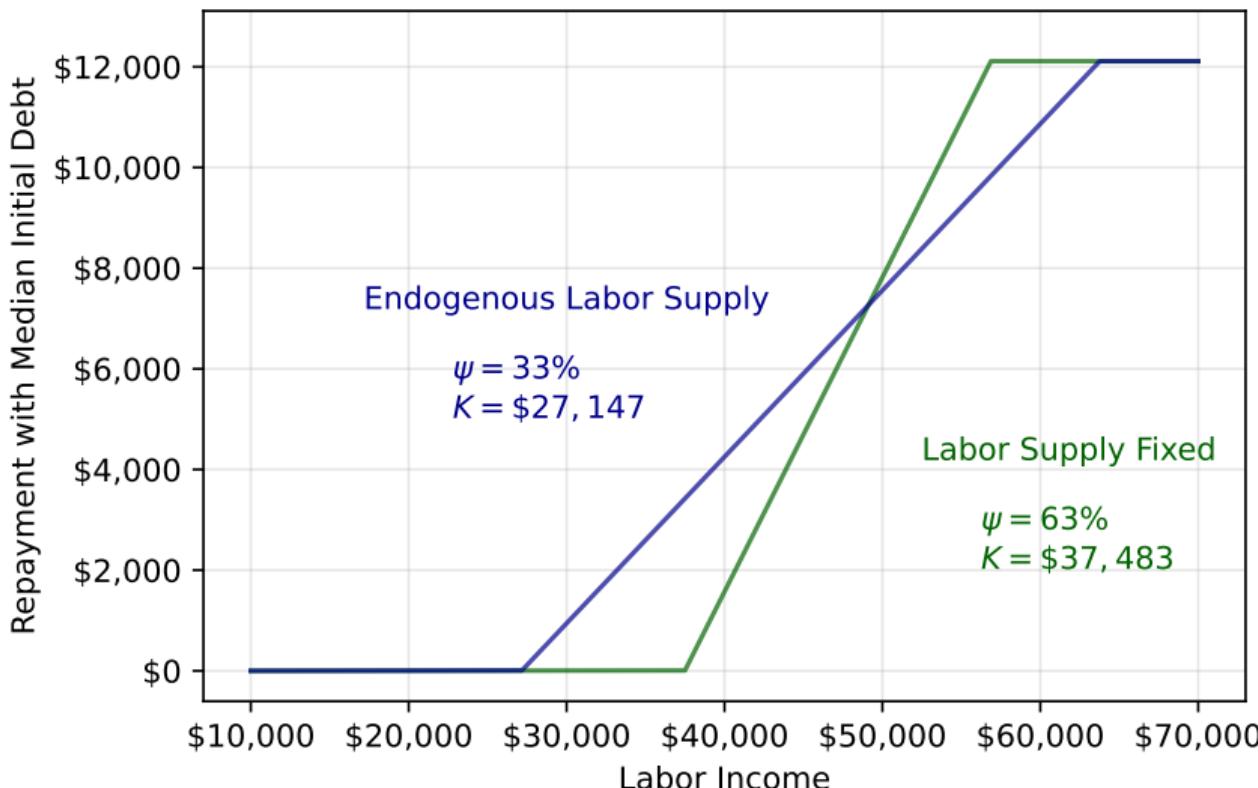

# SOLUTION TO CONSTRAINED-PLANNER'S PROBLEM

▶ Smooth Contract

▶ Compare with Existing

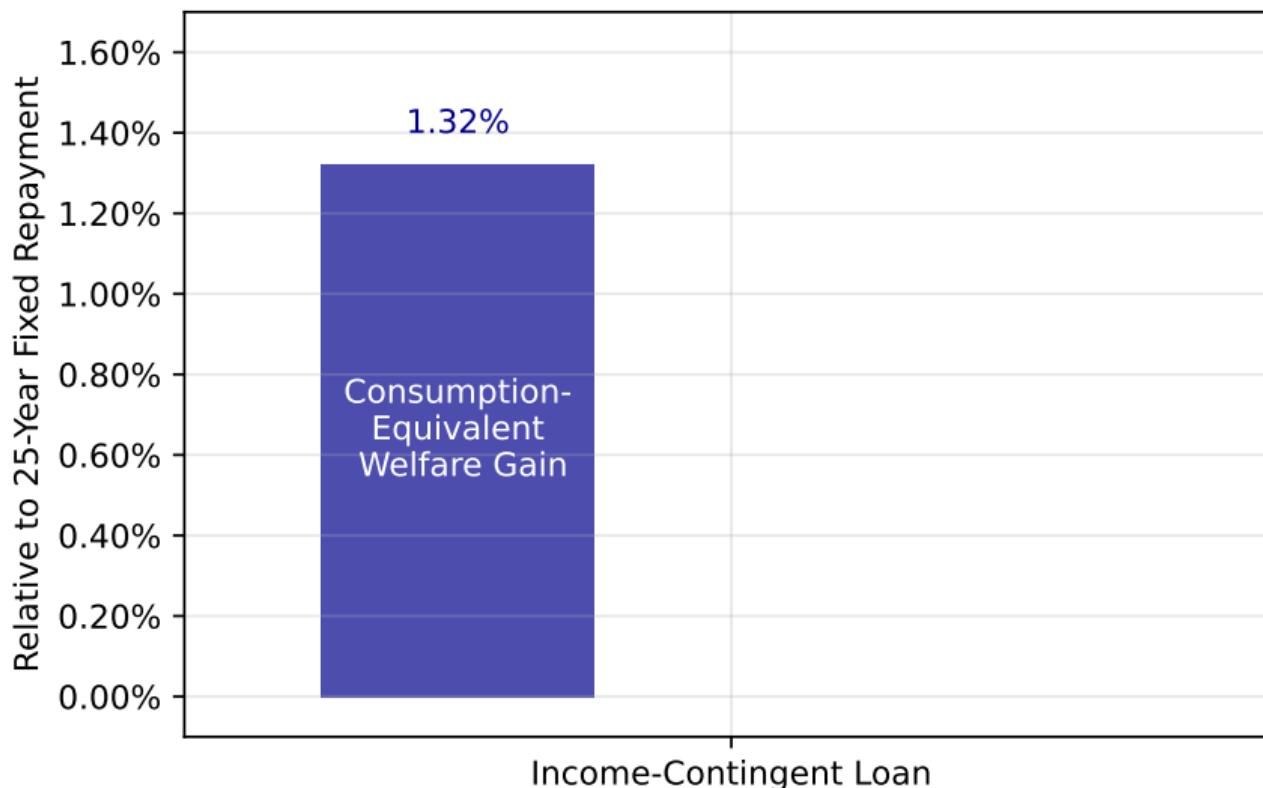

# SOLUTION TO CONSTRAINED-PLANNER'S PROBLEM

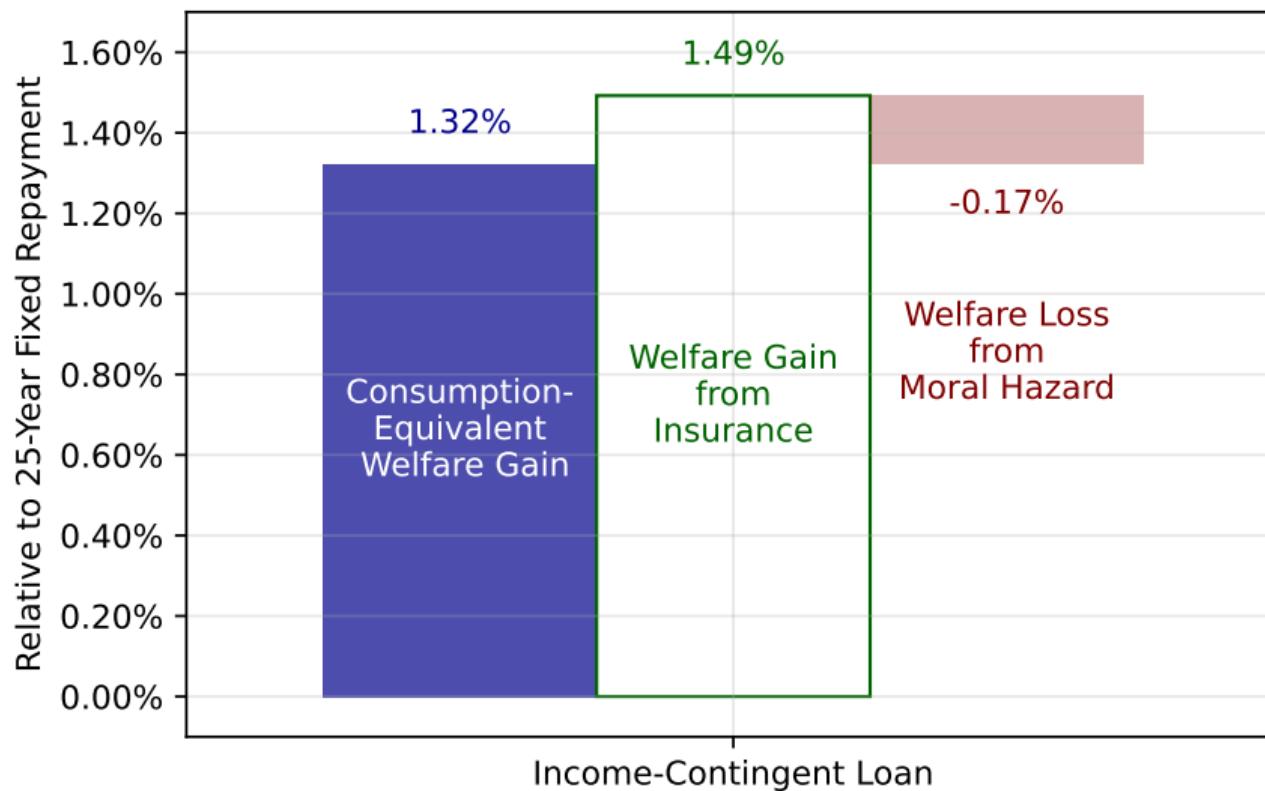

► Smooth Contract

► Compare with Existing

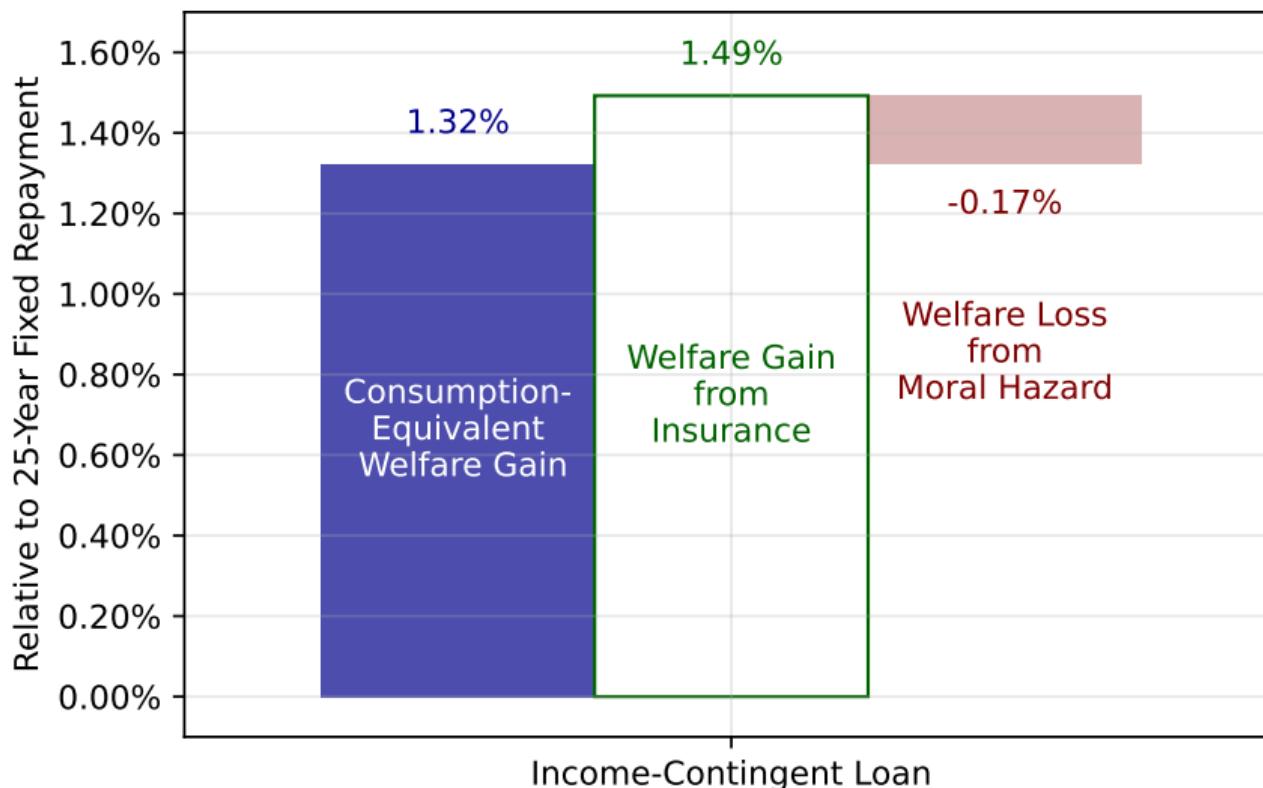

# CONSTRAINED-OPTIMUM = 1.3% INCREASE IN LIFETIME CONSUMPTION

# CONSTRAINED-OPTIMUM = 1.3% INCREASE IN LIFETIME CONSUMPTION

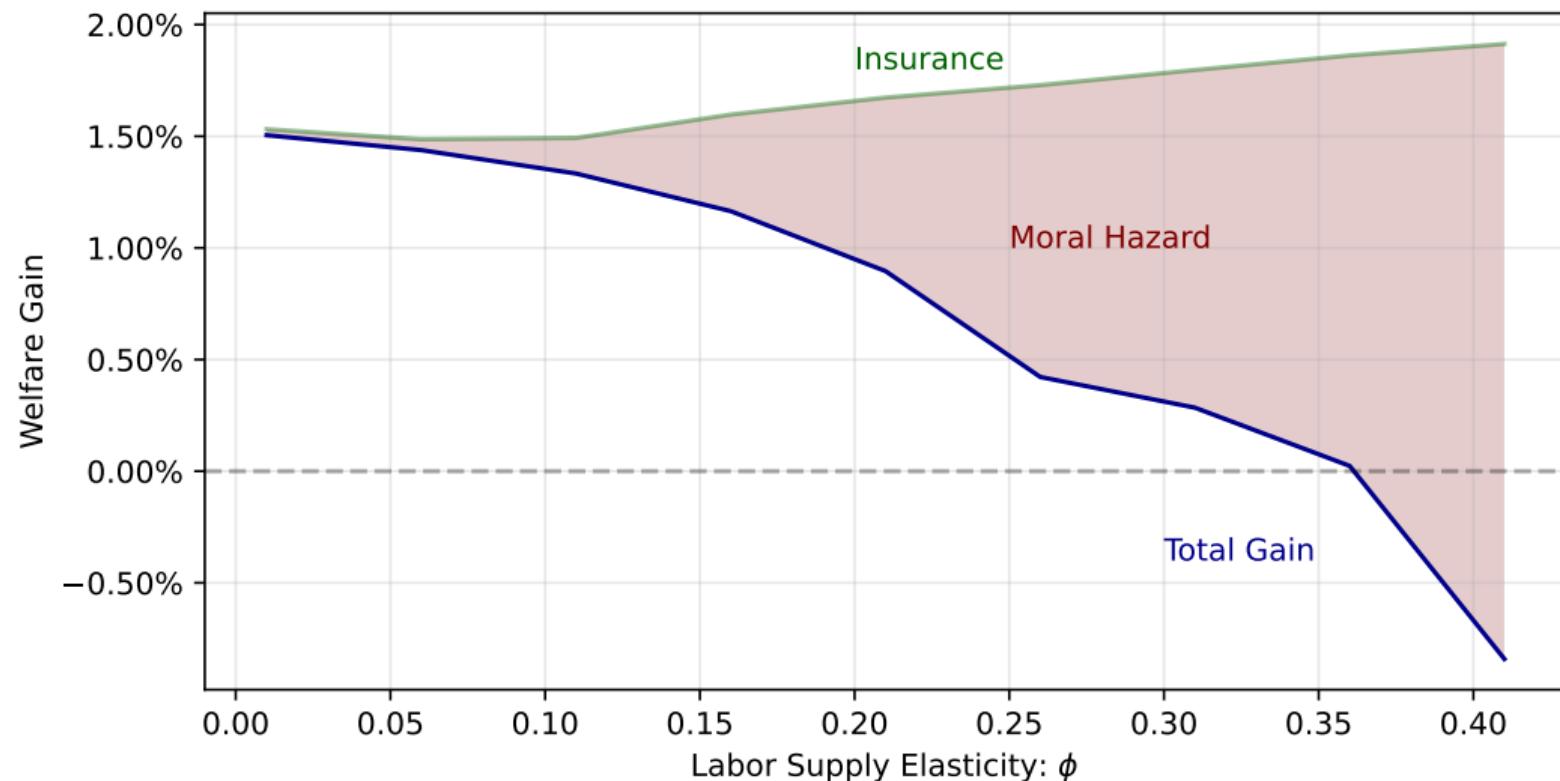

# CONSTRAINED-OPTIMUM = 1.3% INCREASE IN LIFETIME CONSUMPTION

- ▶ Heterogeneity
- ▶ Restrict  $\psi \leq 10\%$
- ▶ Robustness: Alt. Models
- ▶ Robustness: Frictions

# WELFARE GAIN IS POSITIVE AS LONG AS $\phi < 0.37$

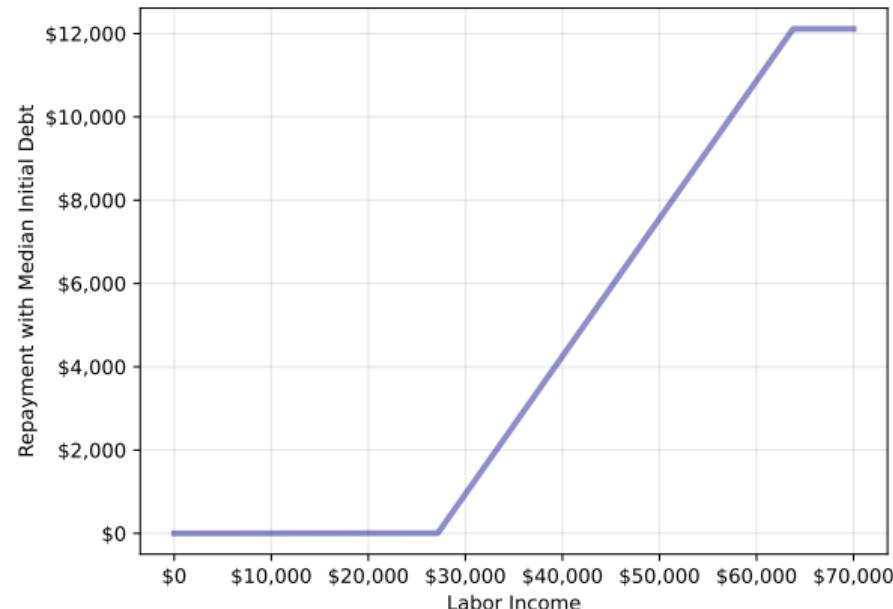

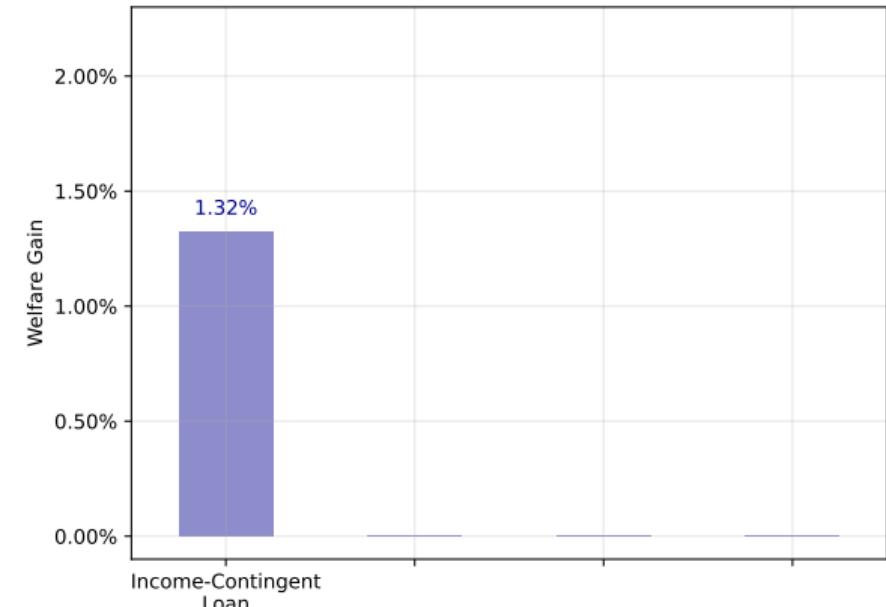

▶ Implied Bunching at  $\phi = 0.37$

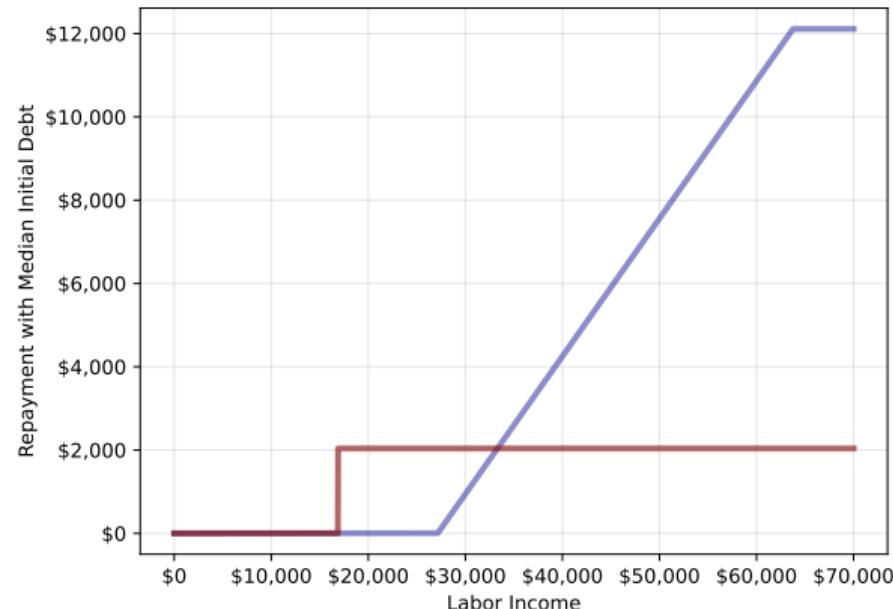

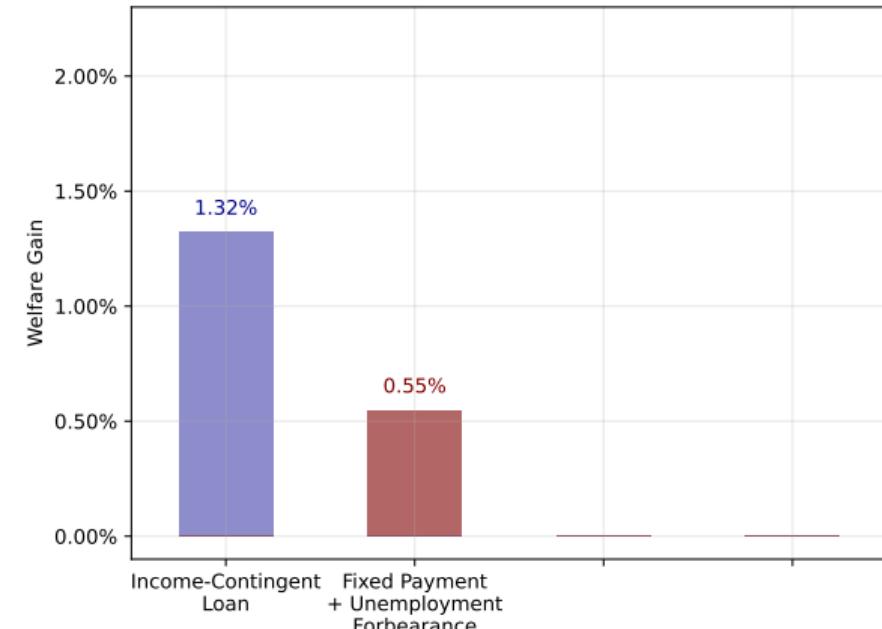

▶ Contracts by  $\phi$

▶ Contracts to Reduce MH

## NEXT: ICLs vs. OTHER CONSTRAINED-OPTIMAL CONTRACTS...

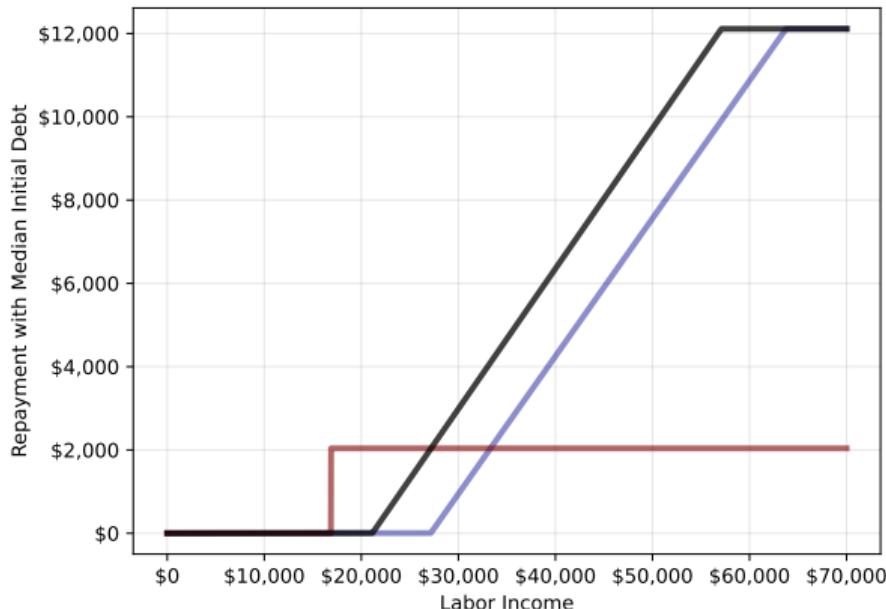

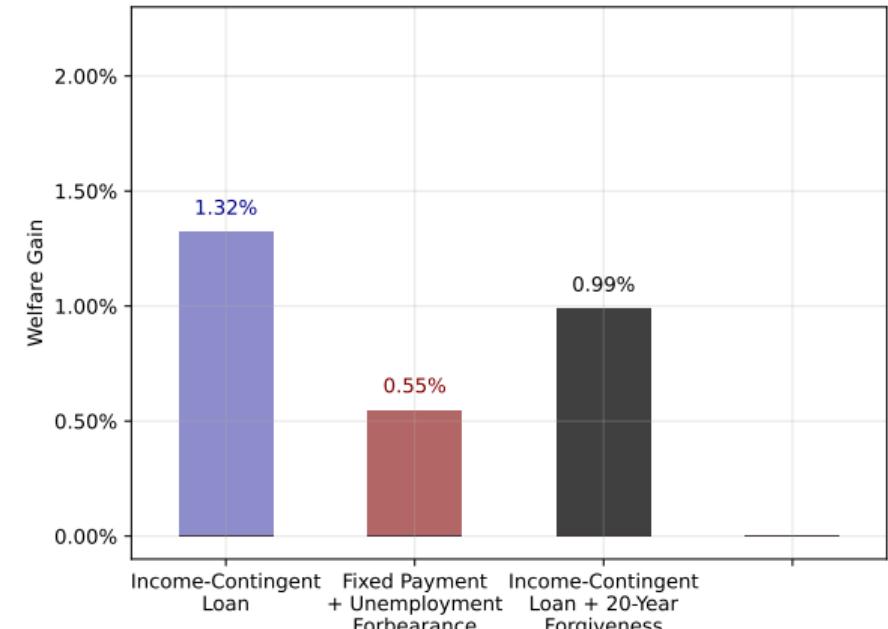

# JUST PROVIDING FORBEARANCE GIVES SMALLER GAINS

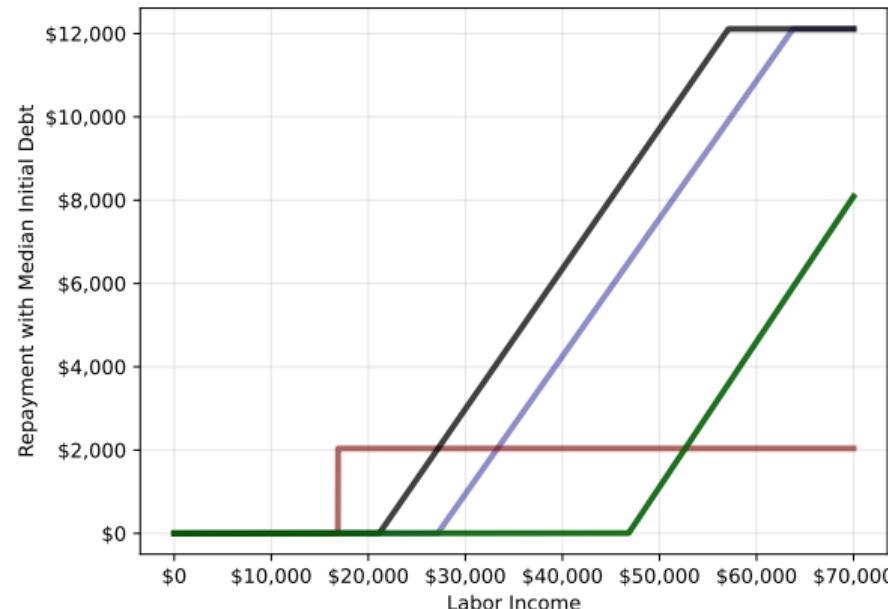

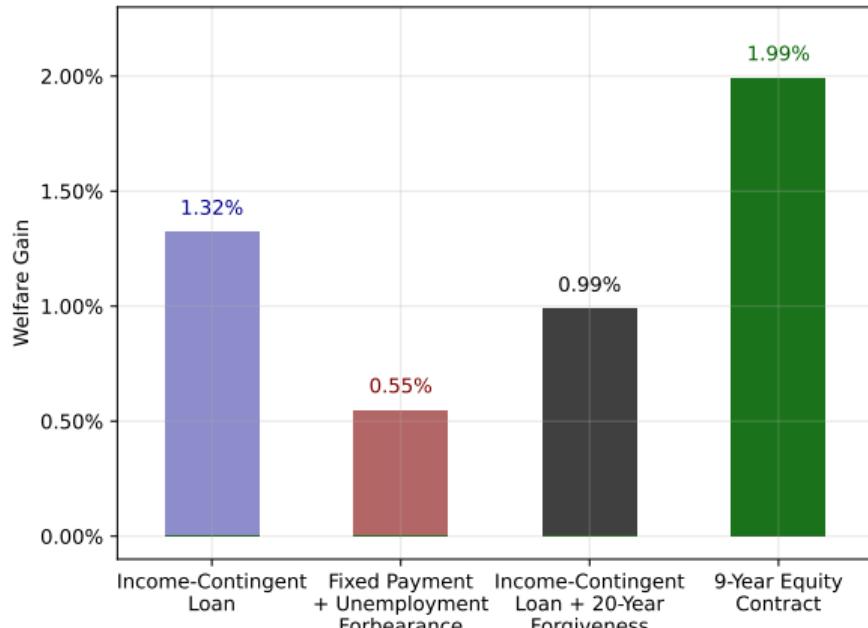

- **Benefit** of income-contingent loan: accelerate payments from high-income

# ADDING FORGIVENESS REDUCES WELFARE GAINS

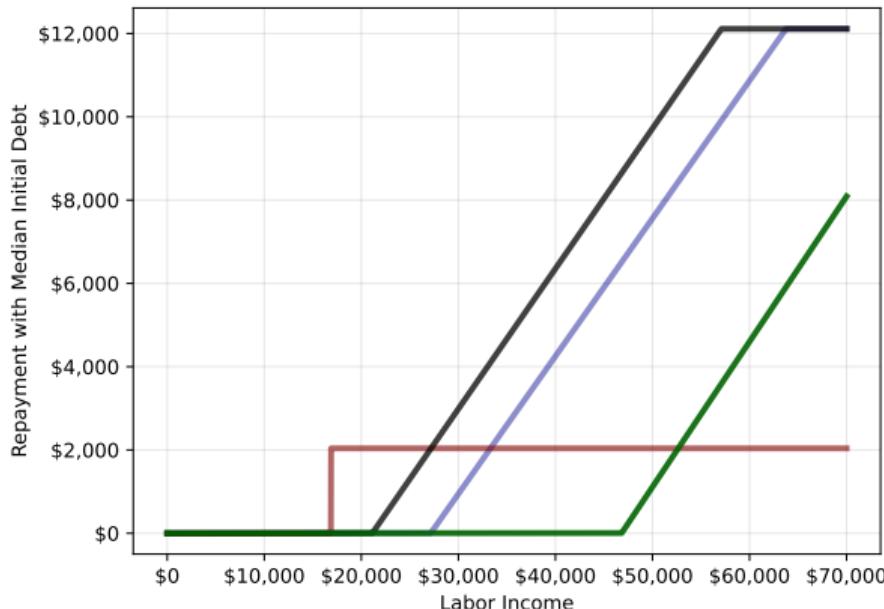

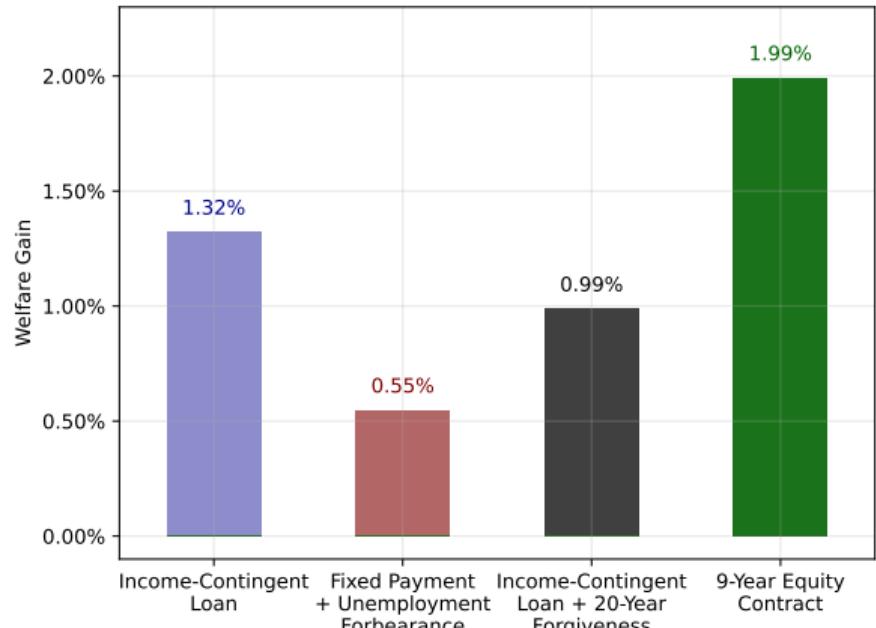

- **Costs** of forgiveness: transfer repayments to young and finite repayment horizon

# EQUITY CONTRACT GIVES LARGER GAINS

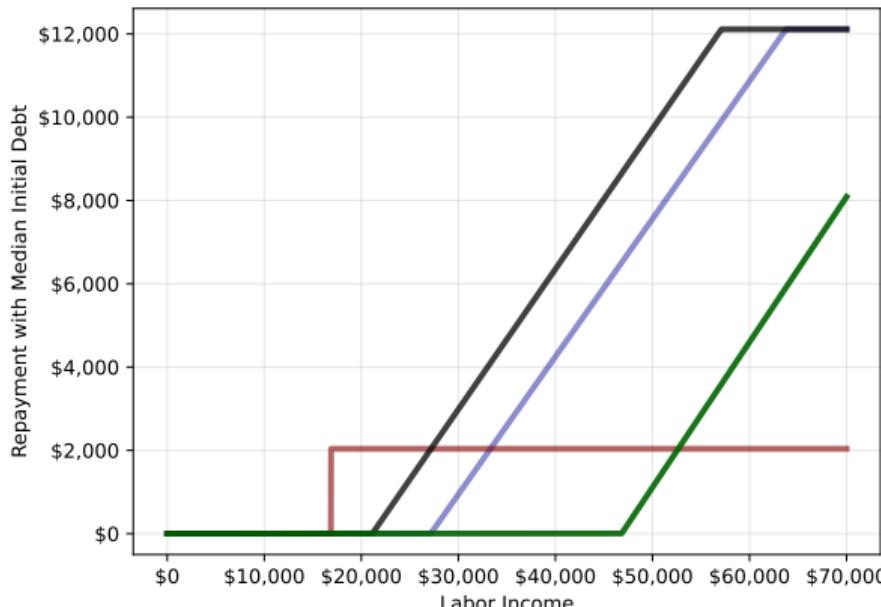

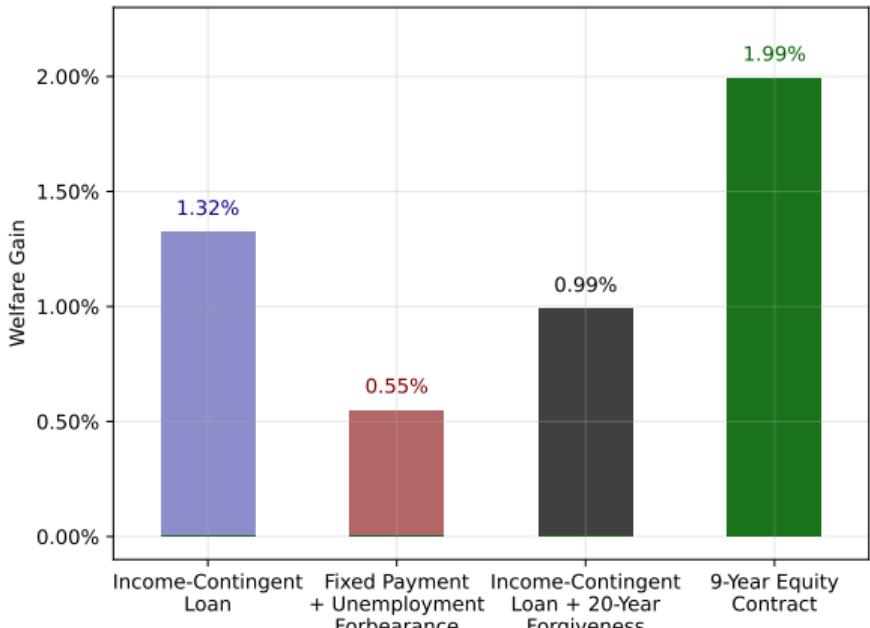

- **Benefit of equity:** uncapped payments from high-income  $\Rightarrow$  70% higher threshold

# EQUITY CONTRACT GIVES LARGER GAINS, BUT MORE DISPERSED

- **Cost** of equity: more likely to cause **ex-ante** responses and **selection**

# EQUITY CONTRACT GIVES LARGER GAINS, BUT MORE DISPERSED

- **Cost** of equity: more likely to cause **ex-ante** responses and **selection**

► Heterogeneity   ► Loss from Endogenous Selection   ► Restructuring   ► Additional Results

# OUTLINE

- 1 Institutional Background and Data
- 2 Labor Supply Responses to Income-Contingent Repayment
- 3 Life Cycle Model with Endogenous Labor Supply
- 4 Welfare and Fiscal Impacts of Income-Contingent Repayment
- 5 Conclusion

- US “student debt crisis”: 25% of borrowers default within 5 years of graduation
  - Possible solution = change contracts to be **income-contingent** (e.g., SAVE)
- **This paper:** evidence + model to calibrate the effects of different contracts
  - ① Ex-post moral hazard is not a reason to avoid **income-contingent** contracts
  - ② Among these contracts, **income-contingent loans** are relatively effective and robust
- **Open question:** effects of income-contingent contracts on ex-ante choices?
- **Broader question:** is more state-contingent repayment useful for other liabilities?
  - HHs: government-provided shared-appreciation mortgages (UK, Canada)
  - Firms: revenue-based financing

## VARIABLE DEFINITIONS

- HELP Income = Taxable Income + Fringe Benefits + Foreign Employment Income + Investment or Property Losses + Employer Super Contributions
- Labor Income = Salary/Wages + Allowances & Tips + Self-Employment Income
- Capital Income = Interest and Dividend Income + Annuity Income + Capital Gains + Rental Income + Managed Trust Income
- Net Deductions = Labor Income + Capital Income - HELP Income

◀ Back

# AU-US DIFFERENCES MOST LIKELY TO AFFECT CONTRACT DESIGN

- ① More debt in US due to higher tuition, longer degrees, and discretionary items
  - Larger demand for insurance in US, but also more moral hazard
  - Discretionary borrowing in US ⇒ possible ex-ante moral hazard
- ② Active private market in US cream-skims high-income borrowers Bachas 2019
  - Amount of insurance that can be provided might be lower in US
- ③ Student loans more subsidized in Australia than US
  - Different moral hazard in US (if there is selection on moral hazard) Karlan-Zinman 2009
- ④ Tuition and enrollment caps at public universities in Australia
  - Supply-side responses could increase fiscal cost of ICLs in US Kargar-Mann 2023
  - Note: I compare contracts with identical subsidy

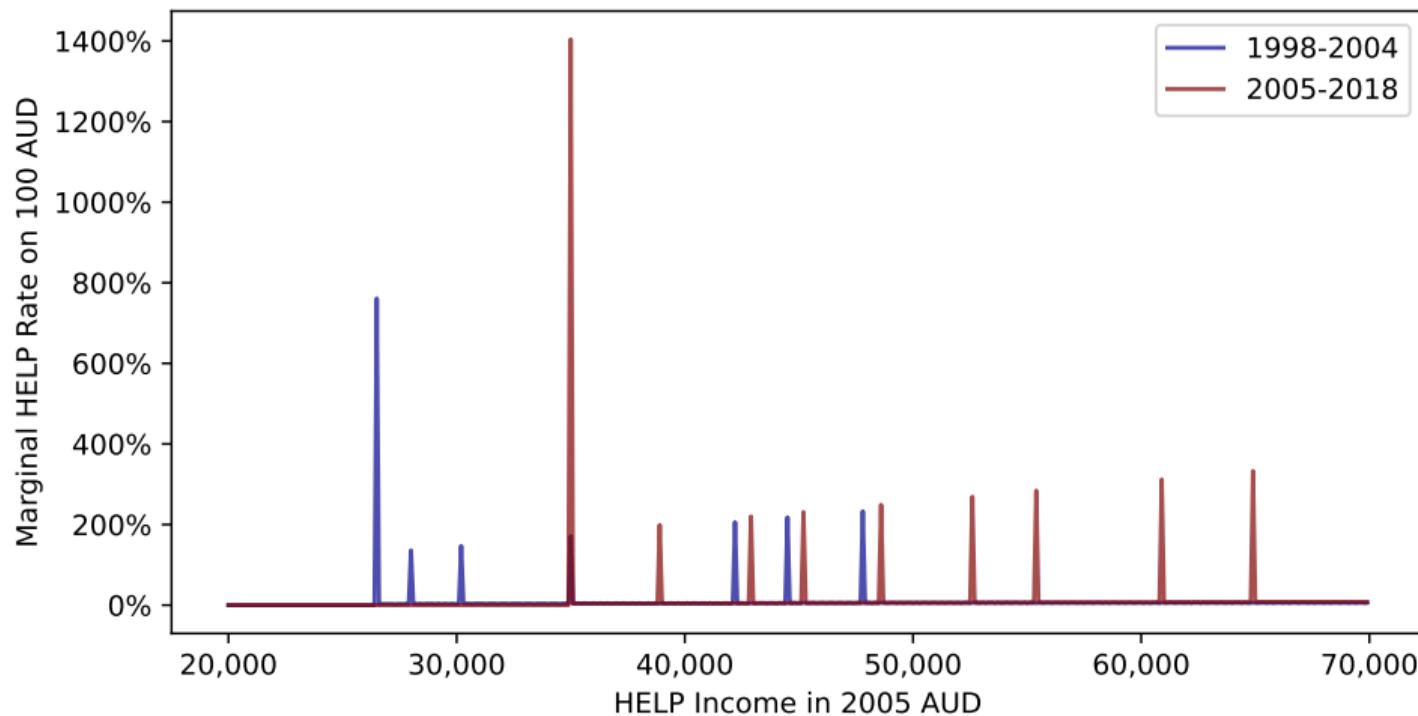

# DIFFERENCES BETWEEN AUSTRALIA AND US: STATISTICS

Feature of Environment	Australia	US
<b>Cost of Higher Education</b>		
Public Undergraduate Tuition Cost	\$2,700–\$10,100 USD per year for CSPs	\$9,500 USD per year for 4-Year In-State \$39,000 USD per year for 4-Year Private Nonprofit
Total Cost of Attendance	\$15,850 USD per year	\$22,700 USD per year
Prevalence of Scholarships	Rare	Common
Initial Student Debt Borrowed	\$8,100–\$30,300 USD	\$51,800 USD (Average)
<b>Student Population</b>		
% of Population with Undergraduate Degree	38%	32%
% of Undergraduates at Private Universities	6%	26%
% of Undergraduates from Abroad	16%	5%
% of Current Students Employed	50%	40%
<b>Income Distribution and Taxes/Transfers</b>		
Median Personal Income	\$33,500 USD	\$40,500 USD
Poverty Line for Single Individual	\$16,200 USD	\$14,580 USD
Gini Coefficient for Income	0.32	0.38
Marginal Tax Rate at Average Income	41%	41%
Heathcote et al. (2017) Tax Progressivity	0.133	0.184
1-Month Individual UI Replacement Rate	23%	35%
Union Membership Rate	13.7%	10.3%

## Ease HECS burden on students, say universities

Kate Marshall

Jan 9, 2003 – 11.00am

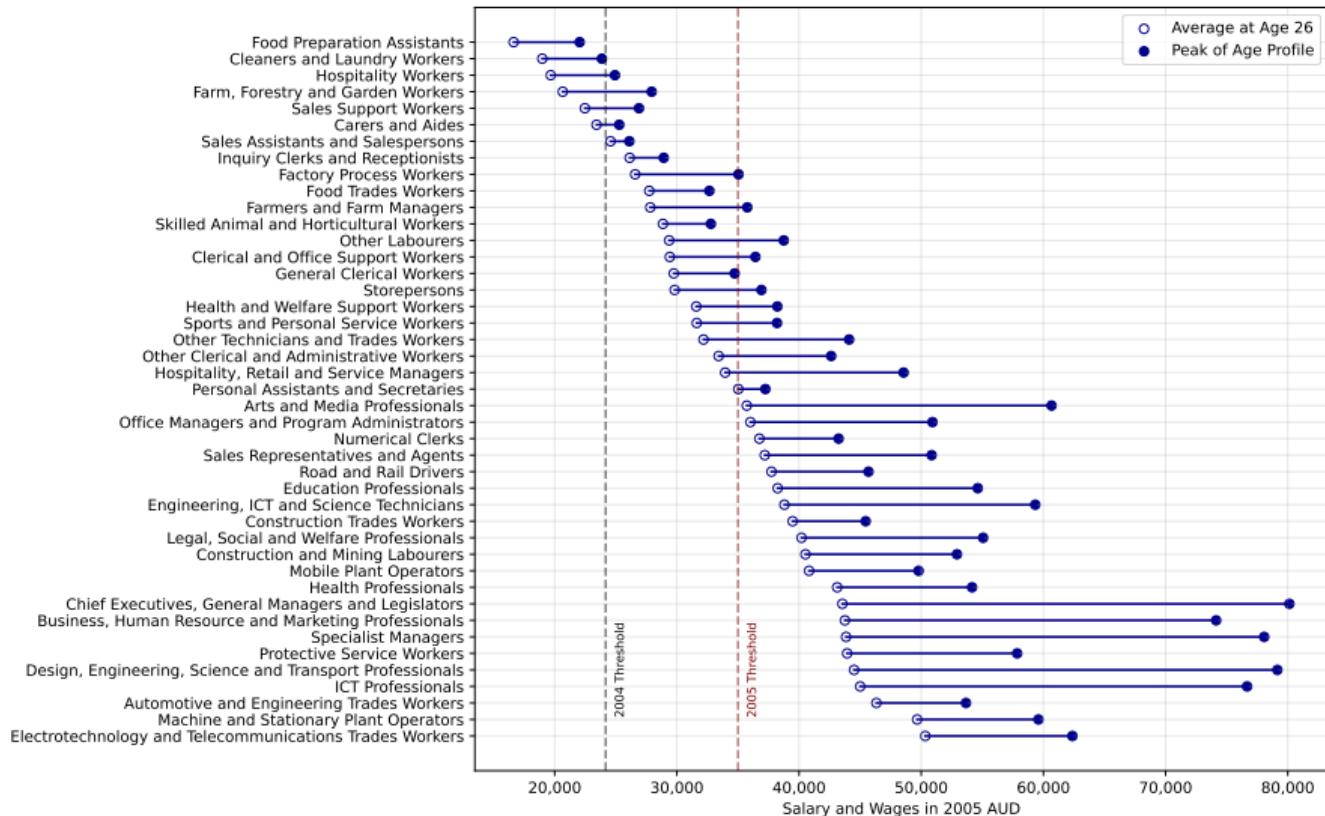

Save

Share

Australian students owing more than \$9 billion of debts to the federal government should be spared financial heartache under a proposal to lift the income threshold for repayments, the Australian Vice-Chancellors Committee said yesterday.

## COMPUTATION OF BUNCHING STATISTIC

- Bunching statistic calculated as in prior literature Chetty et al. 2011, Kleven-Waseem 2013

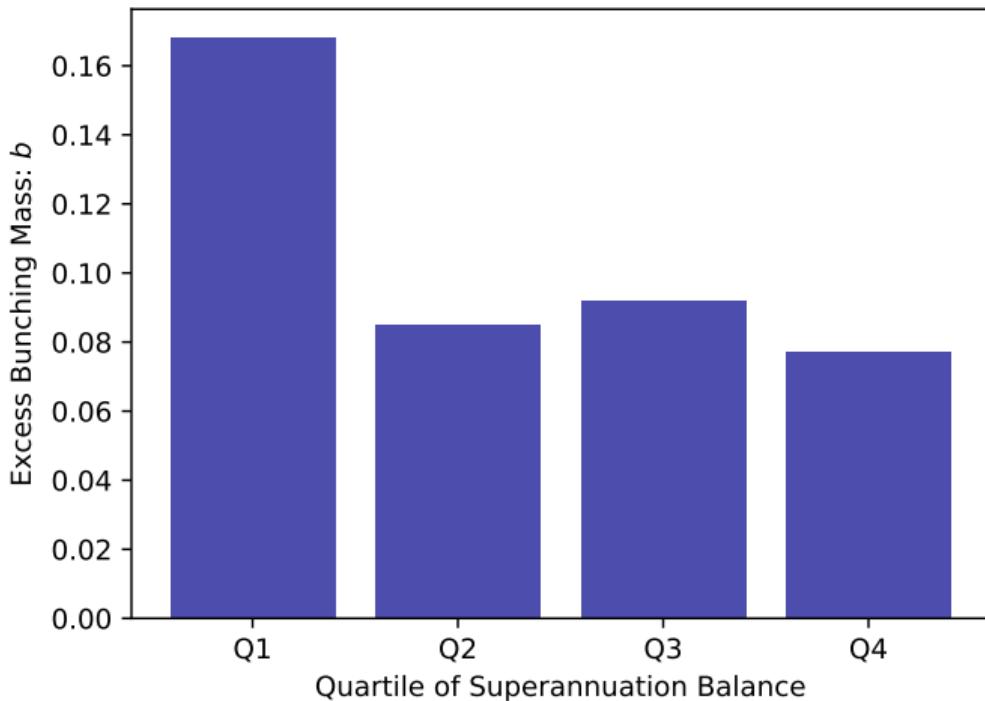

- Fit 5-piece spline leaving out  $[\$32,500, \$35,000 + X]$   $\Rightarrow$  **counterfactual density**
- Iterate and choose  $X$  so that counterfactual density integrates to 1
- 

$$b = \frac{\text{observed mass in } [\$32,500, \$35,000]}{\text{counterfactual mass in } [\$32,500, \$35,000]} - 1$$

- $b = 0.1 \Rightarrow$  10% more people below threshold than would be absent discontinuity
  - Note: normalization makes  $b$  comparable across distributions of different shapes
- Sample:** All debtholders age 20 to 64 pooled across 2005 to 2018
  - Income deflated to 2005 so 0% threshold constant in real terms at **\$35,000**

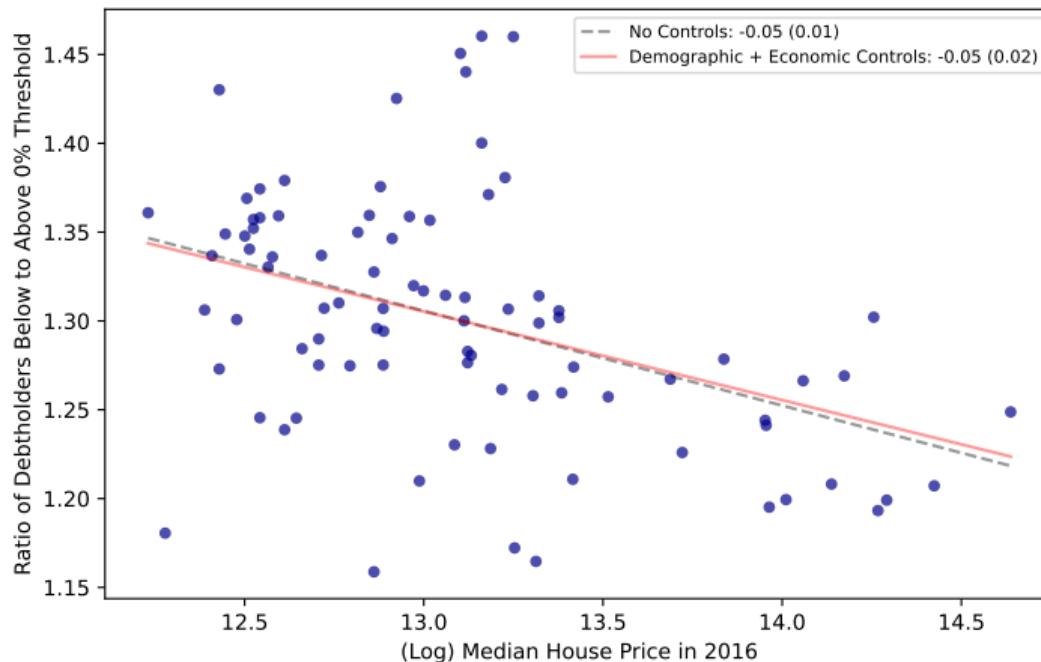

◀ Back

◀ Back

# ADDITIONAL EMPIRICAL RESULTS

- ① **Persistence** of bunching below threshold lasts around three years 
- ② No discontinuity in probability of **switching occupations** around threshold 
- ③ Limited heterogeneity in bunching with household **demographics** 
  - Caveat: no extensive margin responses, which can vary across groups Saez et al. 2012
- ④ Limited evidence of bunching coming from **firm responses** (as in Chetty et al. 2011) 
- ⑤ Additional tests for **evasion**:
  - Bunching present in **salary and wages**, which is harder to misreport Slemrod 2019 
  - Minimal difference in bunching based on **filing type** 
  - Bunching declines by only 4% when dropping **self-employed** 
  - Borrowers are median income  $\Rightarrow$  less avoidance opportunities Slemrod-Yitzhaki 2002

## SECOND-STAGE SIMULATED MINIMUM DISTANCE: OTHER MOMENTS

$$\text{Parameters} = \left( \underbrace{\phi \ f \ \lambda \ \kappa \ \beta}_{\text{preferences}} \quad \underbrace{\delta_0 \ \delta_1 \ \delta_2 \ \delta_0^E \ \delta_1^E}_{\text{wage profile}} \quad \underbrace{\rho \ \sigma_\nu \ \sigma_\epsilon \ \sigma_i}_{\text{wage risk}} \right)$$

- Age profiles of salary & wages  $\Rightarrow$  wage profile parameters
- Moments in Guvenen et al. 2022  $\Rightarrow$  wage risk parameters
- Average capital income at ages 40-44  $\Rightarrow$   $\beta$
- Average labor supply  $\Rightarrow$   $\kappa$

◀ Back

## COMPARISON WITH EXISTING LITERATURE ON LABOR SUPPLY (1/2)

Source: intensive-margin Hicks and Frisch elasticities in Keane (2011) and Chetty (2012)

## COMPARISON WITH EXISTING LITERATURE ON LABOR SUPPLY (2/2)

### Reasons why frictionless elasticity may be smaller/frictions larger:

- ① Different **sample** of college graduates: less flexibility and further from  $y_t = w_t l_t$
- ② Elasticity is **local** to threshold: no high-income individuals Gruber-Saez 2002
- ③ Bunching does not identify **extensive** margin responses Saez et al. 2012

### Contributions:

- ① **Empirical** characterization of responses to income-contingent repayment
  - $\ell_t$  of indebted households responds to liquidity not wealth, like  $c_t$  Ganong-Noel 2020
- ② **Dynamic** model of labor supply with time- and state-dependent adjustment
  - ✓ First paper (to my knowledge) to explicitly estimate different types of frictions

## MODEL FIT: OTHER TARGET MOMENTS

Estimation Target	Data	Model
Average Labor Income	\$42,639	\$45,582
Cross-Sectional Variance of Log Labor Income at Age 22	0.453	0.462
Cross-Sectional Variance of Log Labor Income at Age 32	0.555	0.491
Cross-Sectional Variance of Log Labor Income at Age 42	0.577	0.525
Cross-Sectional Variance of Log Labor Income at Age 52	0.539	0.580
Cross-Sectional Variance of Log Labor Income at Age 62	0.608	0.657
Linear Age Profile Term	0.077	0.080
Quadratic Age Profile Term	-0.001	-0.001
Education Income Premium Constant	-0.574	-0.554
Education Income Premium Slope	0.023	0.023
10th Percentile of 1-Year Labor Income Growth	-0.387	-0.392
10th Percentile of 5-Year Labor Income Growth	-0.667	-0.705
90th Percentile of 1-Year Labor Income Growth	0.415	0.393
90th Percentile of 5-Year Labor Income Growth	0.698	0.710
Average Labor Supply	1.000	0.963
Average Capital Income between Ages 40 and 44	\$1,338	\$1,332

◀ Back

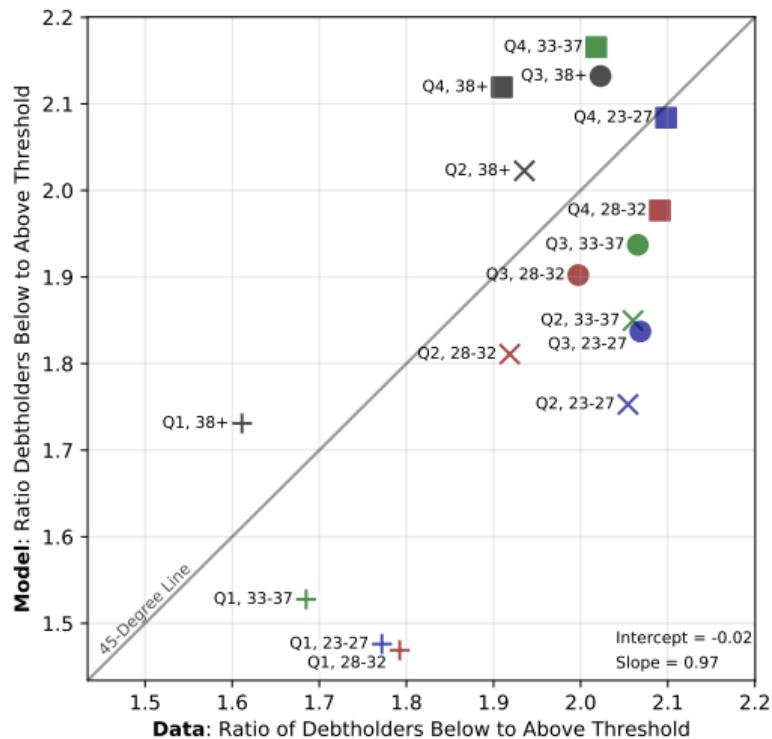

## ADDITIONAL MODEL RESULTS: POSITIVE

- ① **Robustness:**  $\hat{\phi} = 0.111$  with linear adjustment costs (vs. 0.114) 
- ② **Validation** of baseline model on nontargeted moments: 
  - Matches heterogeneity in bunching by debt and age, while LBD model cannot 
  - Replicates bunching at changes in marginal income tax rates
- ③ **P(Repayment)** matters:
  - Counterfactual with indefinite repayment  $\Rightarrow$  bunching  $\uparrow 70\%$  
  - Ignoring dynamic incentives  $\Rightarrow \hat{\phi} \downarrow 40\%$  
- ④ **Liquidity** matters: risk-free borrowing up to natural limit  $\Rightarrow$  bunching  $\downarrow 90\%$  
- ⑤ **Laffer curve**: revenue-maximizing linear tax rate close to static model 

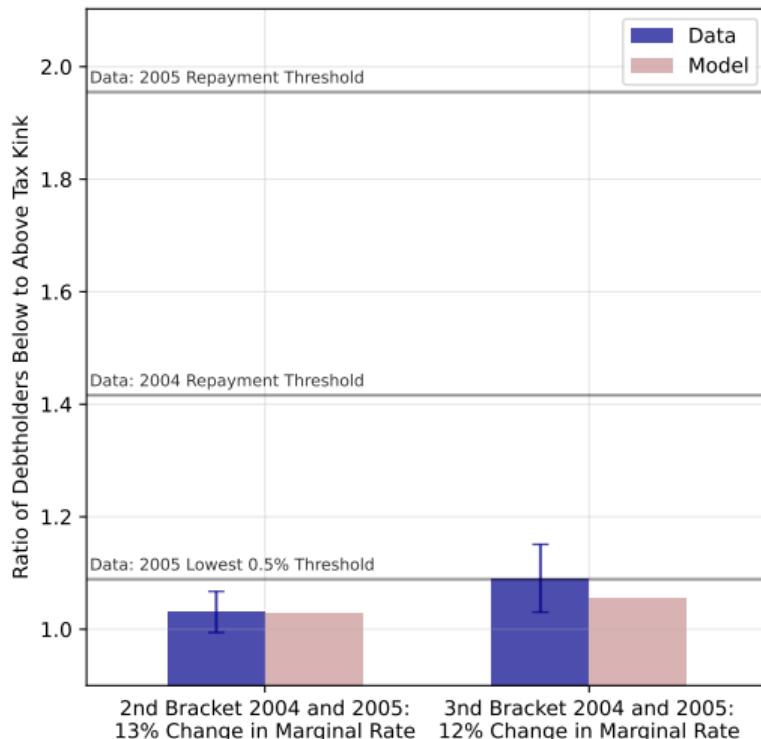

◀ Back

# EFFECTS OF ENDOGENOUS CONTRACT SELECTION

	Constrained-Optimal Contract	
	Income-Contingent Loan	9-Year ISA with Threshold
% Choose 25-Year Fixed Repayment	29%	24%
Borrower Value of Selection	\$180	\$1,544
Fiscal Impact of Selection	-\$757	-\$6,841
<b>Consumption-Equivalent Welfare Gains</b>		
Contract Mandated	1.32%	1.99%
Selection + Taxes to Balance Budget	1.29%	1.64%
Welfare Impact of Selection	-0.03%	-0.35%

- Borrowers choose between two contracts after learning  $s_0$
- After balancing budget, selection **reduces** welfare à la Hirshleifer (1971)

◀ Back

# EFFECTS OF RESTRUCTURING FROM 25-YEAR FIXED REPAYMENT

- To do: effects of endogenous **opt-out** and optimal **restructuring** contract

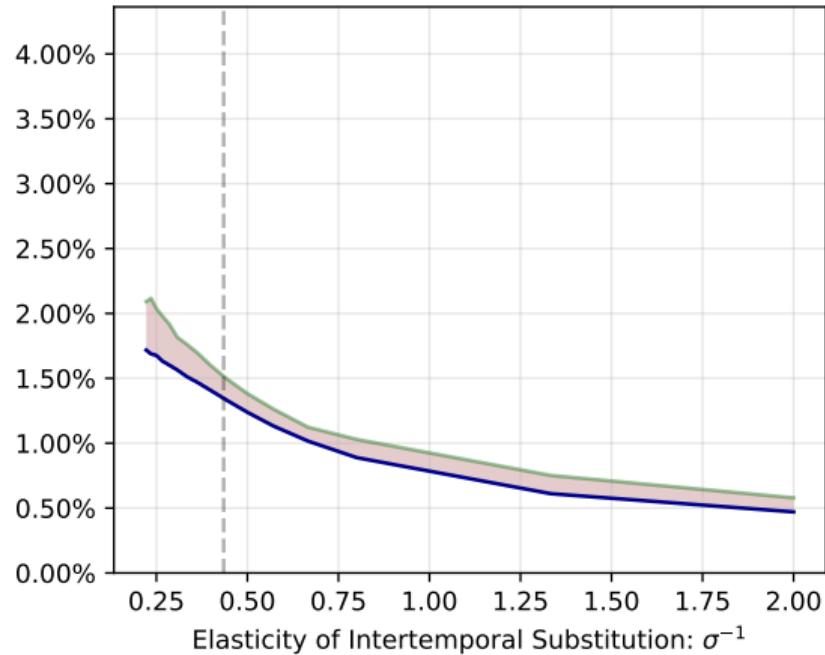

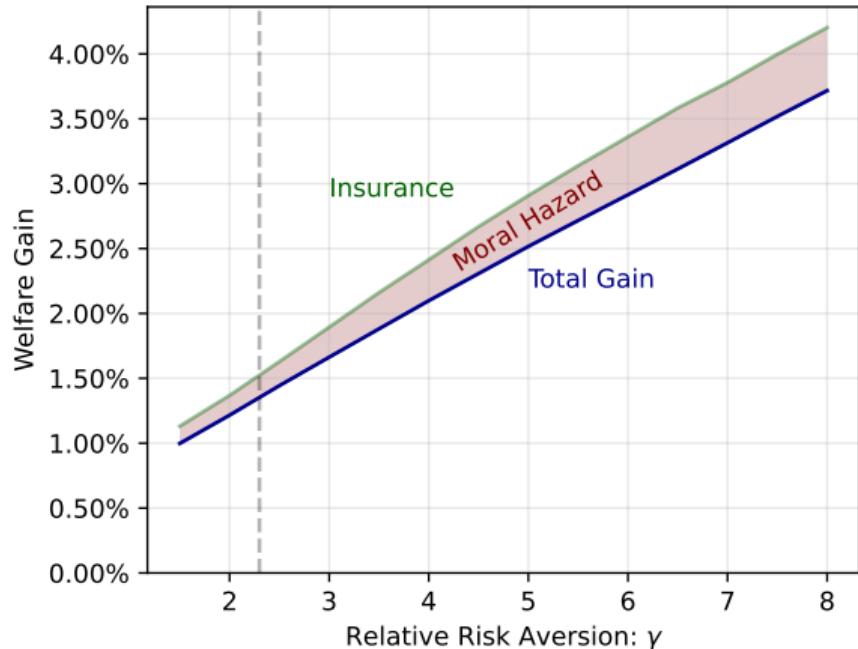

◀ Back

## ADDITIONAL MODEL RESULTS: NORMATIVE

- ① Welfare gains are more sensitive to **risk aversion** than EIS 
- ② Planner's problem is more sensitive to **fixed cost** than Calvo probability 
- ③ No welfare loss from discontinuity in **average** repayment rate 
- ④ **Pure equity** contract does worse than income-contingent loan 
- ⑤ No welfare gain from **combining** forbearance with income-contingent loans 
- ⑥ With **optimal tax** progressivity, forbearance is enough and gains are smaller 
- ⑦ Robustness to **model mispecification**  and **alternative frictions**
